In the cathedral there is a Pietà in marble by Giovanni da Bologna. Opposite the palace is the church of S. Domenico, a Gothic building with a good early Renaissance portal and a relief in the lunette by Luca della Robbia (1449). S. Francesco has a fine 14th century portico and campanile, and a handsome portal of a chapel in the interior by Constantino Trappola (15th century) S. Bernardino, outside the town, is a plain early Renaissance structure. On the walls of the chapel of San Giovanni Battista are frescoes by Lorenzo and Giacomo Salimbeni da San Severino (1416) The modest house where Raphael was born and spent his boyhood forms a museum of engravings and other records of Raphael's works. A monument was erected to him in the piazza in 1897 The theatre, decorated by Girolamo Genga, is one of the earliest in Italy, in it was performed the first Italian comedy, the *Calandra* of Cardinal Bibbiena, the friend of Leo X and Raphael. The magnificent library formed by the Montefeltro and Della Rovere dukes was incorporated in the Vatican library in 1657. There is a free university founded in 1506.

The ancient town of *Urvinum Metaurense* takes its name from the river Metaurus. The walls can be traced. It was important in the Gothic wars, and is mentioned by Procopius. About the end of the 12th century Urbino came under the rule of the family of Montefeltro, and especially of Federigo da Montefeltro, lord of Urbino from 1444 to 1482, who was an unusually enthusiastic patron of art and literature.

Federigo da Montefeltro much strengthened his position by his own marriage with Battista Sforza, and by marrying his daughter to Giovanni della Rovere, the favourite nephew of Pope Sixtus IV, who conferred upon Federigo the title of duke. Federigo's only son Guidobaldo, who succeeded his father, married in 1489 the gifted Elizabeth Gonzaga, of Mantua. Guidobaldo in 1508 bequeathed his coronet to Francesco Maria della Rovere, nephew of Julius II In 1626 the last descendant of Francesco, Francesco Maria II, abdicated in favour of Pope Urban VIII, and Urbino, with its subject towns, which included Pesaro, Fano, Fossombrone, Gubbio, Castel Durante and Cagli together with outlying small villages, about 300 in number, became incorporated in the domain of the Papal States.

During the reigns of Federigo and Guidobaldo, Urbino was one of the foremost centres of activity in art and literature in

Italy. Here Piero della Francesca wrote his celebrated work on the science of perspective, Francesco di Giorgio Martini his *Trattato d' architettura* and Giovanni Santi his poetical account of the chief artists of his time

Throughout the 16th century the state of Urbino manufactured majolica, especially at Gubbio and Castel Durante. Most of the finest pieces were made for the dukes Famous citizens include the Ferrarese painter and friend of Raphael, Timoteo della Vite, and Brumante (*q v*).

This city was also the birthplace of Pope Clement XI, of several cardinals of the Albani family, and of Raffaelle Fabretti, and other scholars.

URDU, the name of that variety of Hindōstānī which borrows a great part of its vocabulary from Persian and Arabic, as contrasted with "Hindi," the variety which eschews such words, but borrows from Sanskrit instead. It is spoken by Moslems and those Hindus who have come under Moslem influence, and has a considerable literature *See* HINDŌSTĀNĪ LANGUAGE and HINDŌSTĀNĪ LITERATURE.

UREA or CARBAMIDE, a colourless crystalline substance known after 1773 as a constituent of urine. It is the chief nitrogenous end product of the metabolism of proteins (*q v.*) in all mammals and some fishes. (For birds, reptiles and most fishes, the corresponding product is uric acid) It is present not only in the urine of mammals but also in their blood, bile, milk, perspiration and other body fluids Moreover, it has been recognized in many lower forms of animal life and has been identified in certain plants and in fungi and moulds. Human urine contains 2 to 5% of urea, which is excreted by an adult man to the extent of about 30 grams (1 oz) daily.

In 1773 H. M Rouelle obtained, by alcoholic extraction of the solid residue from evaporated urine, an alkaline nitrogenous substance which on bacterial fermentation yielded carbonic acid and ammonia. Subsequently Antoine F. Fourcroy and Louis N. Vauquelin (1798) prepared urea nitrate from urine, and the isolation of pure urea from this same source was first accomplished by Joseph L Proust in 1821. Friedrich Wohler in 1828 discovered the artificial formation of urea from ammonia and cyanic acid

Urea crystallizes in long rhombic needles or short prisms having a cooling, saline taste. It is readily soluble in water, methyl alcohol and ethyl alcohol, but not in ether or hydrocarbons It melts without decomposition at 132.7° C. (270 9° F.) and sublimes in a vacuum at temperatures just below and up to its melting point. Heating to higher temperatures causes decomposition.

Chemical Properties of Urea.—Urea is the diamide of carbonic acid (*see* AMIDES)—hence the alternative name "carbamide." Its chemical formula was originally given as $NH_2CO NH_2$, but since this formula has seemed to some chemists not to explain the behaviour of urea under all circumstances, a number of others have been proposed. The best view in 1946 seemed to be that urea is a resonance hybrid, receiving contributions from the structure given above and also from the two further structures, $^{+}NH_3=C\overline{O}-NH_2$ and $NH_2-C\overline{O}=\overset{+}{N}H_2$. For reasons of convenience, however, the formula is most commonly written in its original form, $H_2N\,CO.NH_2$, and resonance with the remaining two structures is left implicit.

The above mentioned method of Wöhler for the synthesis of urea consists essentially in the isomerization of ammonium cyanate, NH_4NCO, to urea, $NH_2.CO.NH_2$. This process, however, is a reversible one, and the relative amounts of cyanate and urea depend on reaction conditions.

When urea is heated above its melting point it decomposes at first to yield ammonia, ammonium cyanate and biuret and, at higher temperatures, cyanuric acid and ammelide. If an aqueous solution of it is boiled, urea is partially converted to ammonium cyanate, which in turn is hydrolysed to ammonia and carbon dioxide Heating such a solution in a sealed tube at 180° C. brings about complete decomposition.

Dilute aqueous solutions of acids and alkalis have no action on urea in the cold but, when heated, break it down to ammonia and carbon dioxide. Strong acids yield salts, such as urea nitrate.

Although urea reacts with alcohols to form urethanes (carbamic esters) and with many aldehydes, ketones, anhydrides and other organic compounds, its most important reactions are with formaldehyde to form methylolureas and with malonic acid derivatives to form malonylurea or barbituric acid derivatives

The enzyme *urease*, obtainable from the soy bean and the Jack bean (*Canavalia ensiformis*), brings about the rapid hydrolysis of urea, and this action serves as a convenient method for the determination of urea Other methods sometimes used are the Kjeldahl, the hypobromite and the xanthhydrol.

Commercial Manufacture of Urea.—Many ways have been found to synthesize urea in the laboratory but only (1) the hydrolysis of cyanamide, obtained from calcium cyanamide which is made by the reaction of nitrogen at high temperature with calcium carbide, and (2) the reaction of ammonia and carbon dioxide have been used industrially Method (1) was never employed extensively and by 1936, when world capacity was almost 400,000 lb. per day, only method (2) was in commercial use In this method carbon dioxide and ammonia are continuously injected into a reaction vessel maintained at temperatures up to about 200° C and pressures up to about 5,000 lb per sq in Solid urea is separated from the reaction vessel effluent which contains, besides urea, water and unreacted ammonia and carbon dioxide.

Industrial Uses of Urea.—Urea contains 46.7% of combined nitrogen in a form which is easily and rapidly converted to ammonia in the soil, therefore, it is a much more concentrated nitrogenous fertilizer than ammonium nitrate, ammonium sulphate or sodium nitrate. Moreover, modern manufacturing methods have made it possible to deliver urea to the consumer at about the same cost per unit of nitrogen as the other nitrogen-containing fertilizer materials. It may be used in the making of "mixed goods," containing other fertilizer ingredients, or it may be applied to the land alone. (*See* FERTILIZERS.)

Urea has two important uses in the wood industry—in seasoning and in bending. Green lumber to which urea has been suitably applied can be rapidly kiln-dried without checking. Economies have thus been realized because of saving in time and reduction in loss of material. Dry wood, well-soaked in a hot solution of urea can readily be bent without fracture, the bent wood retaining its shape when dried in a proper form. This procedure is used in boatbuilding, furniture manufacture and basketmaking

Although the nitrogen in urea is in nonprotein form, if urea is fed to a ruminant animal along with fermentable carbohydrate material the micro-organisms in the rumen build its nitrogen into proteins which can be used by the animal through action in the lower digestive tract. Experience has shown that the grain ration fed to the animal must not contain more than 3% urea. Even so, a significant part of the protein requirement can be supplied through the use of urea. In 1943, during World War II, when protein feeds were scarce, this use became important. Urea cannot be utilized by nonruminant animals such as horses, swine and poultry.

Urea is not poisonous, or as pharmacologists prefer to say, it is practically nontoxic. However, it has had little direct use in internal medicine except as a diuretic. Its most important application in medicine has been its employment in the treatment of wounds, and has proved especially valuable in promoting the healing of stubborn types of suppurating infections Urea dissolves dead tissue in which bacteria thrive, and in the resulting clean wound the living cells can successfully combat bacterial invasion, so that healing proceeds rapidly The use of urea has supplanted the use of blowfly maggots and allantoin in the treatment of purulent and stubborn wounds. In fact, maggots are effective since they secrete allantoin, and allantoin is effective because it yields urea in the wound.

Large amounts of urea are used by the pharmaceutical industry in the production of malonylurea and barbituric acid derivatives. Approximately 400 of these derivatives are known, and about 12 are commonly used as soporifics and sedatives under a great variety of trade names.

The most important use of urea other than as fertilizer is in

the production of urea-formaldehyde resins (*See* RESINS. *Synthetic Resins*) The primary reaction of formaldehyde and urea is the formation of water-soluble methylolurea. Application of heat or catalyst, or both, causes further reaction of methylolurea with itself and a hard, insoluble, infusible resin is finally obtained. Urea-formaldehyde resins are widely used in moulded articles, in lacquers and enamels, in the impregnation of paper, wood and textiles, as adhesives for plywood and other materials, as crease-proofing agents for fabrics, etc Although urea reacts with aldehydes other than formaldehyde, the resinous products obtained have no properties which make them useful.

Some of the many other less important uses of urea are as an ingredient in printing pastes, as a liquefying agent in the manufacture of glue, as a stabilizer for certain explosives, as an aid in the preparation of some dyes, as a textile-treating agent and as a nutrient for yeast culture.

Thiourea.—The sulphur analogue of urea, $NH_2.CS.NH_2$, is manufactured on a limited scale for employment in photography, synthetic resins, insecticides, pharmaceuticals and textile-treating agents, and as a starting material for various dyestuffs. It may be prepared (1) by heating ammonium thiocyanate at 160°–170° C.; (2) by the reaction of hydrogen sulphide with cyanamide. Thiourea crystallizes from water in colourless, six-sided prisms or silky needles melting at 180°–182° C.

URETHANE is synthesized from ammonia and ethyl chlorocarbonate or diethyl carbonate by treatment of urea with alcohol under pressure or by the action of warm alcohol on urea nitrate with addition of sodium nitrite. Urethane, ethyl carbamate, $NH_2.CO_2C_2H_5$, crystallizes in large plates, readily soluble in water and melting at 49°–50° and boiling at 184° C. When heated with ammonia to 180° C. it gives urea. Cold alcoholic potassium ethoxide decomposes it into potassium cyanate and alcohol. When treated with concentrated nitric acid it yields nitro-urethane, $NO_2.NH.CO.OC_2H_5$, from which nitramide, $NO_2.NH_2$, may be obtained Physiologically, urethane has a rapid hypnotic action, producing a calm sleep and having no depressant effect on the circulation It is much used as an anaesthetic for animals. Di-urethane, $NH(CO_2C_2H_5)_2$, and hedonal, $NH_2CO_2CH(CH_3).(C_2H_5)$, are also hypnotics. Urethanes have also a decided diuretic effect.

UREY, HAROLD CLAYTON (1893–), U.S. chemist, was born in Walkerton, Ind., April 29, 1893. After receiving his early education in rural schools, he taught in them from 1911 to 1914. He then entered the University of Montana and received the B.S degree in 1917, with major interests in zoology and chemistry. After spending two years as a research chemist in industry and two years as an instructor at the University of Montana, he entered graduate school at the University of California (Berkeley), where he was granted the Ph.D degree in chemistry in 1923. He then spent one year as an American-Scandinavian foundation fellow with Nils Bohr at Copenhagen, Den., followed by 5 years on the staff at the Johns Hopkins university and 16 years at Columbia university. During the period 1939–42 he was executive officer of the department of chemistry at Columbia. In 1945 he joined the newly formed Institute for Nuclear Studies and the department of chemistry of The University of Chicago.

In 1934 Urey was awarded the Nobel prize in chemistry for his discovery of the heavy hydrogen isotope of mass two (deuterium). Later he worked out procedures for the separation of heavy isotopes of carbon, oxygen, nitrogen and sulphur. During the World War II period, 1942–45, he was director of research of the Substitute Alloy Materials laboratories, Columbia university. This project became a part of the Manhattan Engineers District program for the development of the atomic bomb. Urey's group provided the fundamental information for the separation of the fissionable isotope, uranium-235, from the more abundant isotope, uranium-238, by gaseous diffusion, and investigated methods for the concentration of the heavy isotope of hydrogen and for the separation of the boron isotopes. After the war he developed methods for the measurement of temperatures as they existed in the oceans of past geological ages, and developed a theory for the origin of the earth with particular reference to its chemical aspects. (W C. J.)

URFÉ, HONORÉ D', MARQUIS DE VALBROMEY, COMTE DE CHÂTEAUNEUF (1568–1625), French novelist and miscellaneous writer, was born at Marseilles on Feb 11, 1568, and was educated at the Collège de Tsarnon A partisan of the league, he was taken prisoner in 1595, and, though soon set at liberty, he was again captured and imprisoned. During his imprisonment he read Ronsard, Petrarch and above all the *Diana enamorada* of George de Montemayor and Tasso's *Aminta*. Here, too, he wrote the *Epitres morales* (1598). Honoré's brother Anne, comte d'Urfé, had married in 1571 Diane de Châteaumorand, but the marriage was annulled in 1598 by Clement VIII. Anne d'Urfé was ordained to the priesthood in 1603, and died in 1621 dean of Montbrison. Diane had a great fortune, and to avoid the alienation of the money from the D'Urfé family, Honoré married her in 1600 This marriage also proved unhappy, D'Urfé spent most of his time separated from his wife at the court of Savoy.

In Savoy he conceived the plan of his novel *Astrée*, the scene of which is laid on the banks of the Lignon in his native province of Forez. It is a leisurely romance in which the loves of Céladon and Astrée are told with digressions. Some episodes suggest the adventures of Henry IV. The two first parts of *Astrée* appeared in 1610, the third in 1619, and in 1627 the fourth part was edited and a fifth added by D'Urfé's secretary Balthazar Baro. *Astrée* set the fashion temporarily in the drama as in romance, and no tragedy was complete without elaborate discussions on love in the manner of Céladon and Astrée. D'Urfé also wrote two poems, *La Sireme* (1611) and *Sylvanire* (1625). He died from injuries received by a fall from his horse at Villafranca on June 1, 1625, during a campaign against the Spaniards.

URGA: *see* ULAN BATOR.

URI, one of the cantons of central Switzerland The name is popularly derived from *urochs* or *auerochs* (wild bull), a bull's head having been borne for ages as the arms of the region.

The total area is 414.7 sq mi , of which only approximately half (the lowest proportion in the confederation) is reckoned as "productive" (forests covering 48 sq mi.), while 7½ sq.mi. are occupied by a part of the Lake of Lucerne and more than 20% of the unproductive area is covered with glaciers The highest summit in the Uri is the Damma Stock (11,919 ft.), north of the Furka pass Little of the land is capable of further cultivation, for Uri is composed of the torrent section of the upper Reuss, draining, with its tributaries, steep-sided valleys. The chief railway is the main St. Gotthard line. Near Wassen are the remarkable looped and spiral tunnels. There is also an electric railway from Altdorf to its port, Flüelen. Communication is largely by the excellently planned roads which lead to the mountain passes; these give access to the cantons lying east and south; *e.g.*, Glarus (the Klausen pass, 6,404 ft.), the Grisons (Oberalp pass, 6,719 ft.), the Valais (Furka pass, 7,992 ft).

In 1950 the aggregate population was 28,556 (67 to 1 sq.mi.). Of the 1930 population of 22,968, 22,249 were German-speaking, 594 Italian-speaking and 62 French-speaking, while 21,674 were Catholics, 1,251 Protestants and 2 were Jews. After 1814 Uri was administered by the bishop of Coire; previously all the canton except Andermatt (Urseren) was in the diocese of Constance. The capital and largest town is Altdorf (pop. 6,576 in 1950), indissolubly connected with the legend of William Tell (*q.v.*).

Uri was organized as an administrative district containing 20 communes. The legislature until 1928 was a primitive democratic assembly (*Landsgemeinde*) composed of all male citizens of 20 years of age and over. This assembly had met, uninterruptedly, since 1309, usually once annually, near Altdorf The procedure was controlled by many antique ceremonies. After 1928 there was an elected legislature of 49 members. (*See* SWITZERLAND: *Government*.)

History.—Uri is first mentioned in 732 as the place of banishment of Eto, the abbot of Reichenau, by the duke of Alamannia. In 853 it was given by Louis the German to the nunnery (*Frauenmunster*) at Zurich which he had just founded.

and of which his daughter, Hildegard, was the first abbess. As early as 1243 Uri had a common seal, and in the confirmation of its privileges (1274) granted by Rudolf of Habsburg mention is made of its "head-man" (*Amman*) and of the "commune" (*universitas*) It took part, with Schwyz and Unterwalden, in founding the "Everlasting League" (*q v.*) on Aug 1, 1291, defending its liberty in the fight of Morgarten (1315) and renewing the League of the Three at Brunnen (1315). It took part in the victory of Sempach (1386), and (1512) in the conquest of Lugano. At the Reformation Uri clung to the old faith. In 1798, on the formation of the Helvetic republic Uri became part of the huge canton of the Waldstätten and lost all its Italian possessions. In 1803 Uri became an independent canton again, with Ursern, but without the Val Leventina It tried hard to bring back the old state of things in 1814–15, and opposed all attempts at reform, joining the League of Sarnen in 1832 to maintain the pact of 1815, opposing the proposed revision of the pact, and being one of the members of the Sonderbund in 1845. (*See* SWITZERLAND: *History*)

URIC ACID, in organic chemistry, an acid which is one of the penultimate products of the tissue waste in the human body. (*See* PURINES) While the bulk of the nitrogen of the albuminoids is excreted by kidneys and bladder as urea, a small portion of it stops at the uric acid stage Human urine contains only a fraction of a per cent. of the acid, chiefly as sodium salt; abundance of uric acid is met with in the excrement of serpents and birds, in which it is the principal nitrogenous product of tissue waste Pure uric acid, $C_5H_4N_4O_3$, forms a snow-white microcrystalline powder, devoid of smell or taste, soluble in 1,600 and 50,000 parts of water at the boiling and freezing points, respectively For its detection in urine, excess of hydrochloric acid is added; uric acid then separates, generally coloured red by impurities. The precipitate is dissolved in a few drops of nitric acid and after evaporation to dryness the residue on addition of ammonia assumes the intense purple colour of murexide (*q v.*).

URICONIUM (more correctly *Viroconium* or *Vriconium*), *chef-lieu*, as proved by an inscription, of the Cornovii, now Wroxeter on the Severn, 5 m E of Shrewsbury. At first perhaps (47–65) a Roman legionary fortress, held by Legiones XIV. and XX against the Welsh hill tribes. When the garrison was removed, it became a flourishing town with public baths (excavated 1859–61), town hall, and market (excavated 1924–27).

Bibliography—*See* J. P. Bushe-Fox, *Excavations at Wroxeter in 1912, 1913, 1914* (*Soc. Antiq. Research Reports*, I., ii. and iv); G. F. Hill, *Numis. Chron.* (1923), 336; *Report of Excavations* by D. Atkinson (*Birmingham Arch. Soc.*), *in the Press.*

URIM and **THUMMIM,** in the Bible. These descriptive terms are applied to one of the methods of divination employed by the ancient Hebrews, which, it is now generally agreed, consisted in a species of sacred lot. Together with "dreams" and the prophetic oracle it formed the recognized channel by which divine communications were given (*cf.* I. Sam. xxviii. 6). That some method of casting lots is denoted by the terms is evident from I Sam xiv. 41, *f.*

From this illuminating passage it is clear (*a*) that by means of the Urim and Thummim the guilt or innocence of the suspected parties was determined; (*b*) that this was effected by a series of categorical questions implying the simple alternative of "yes" or "no," or something positive or negative. A further inference (*c*) from a comparison of I Sam. xiv. 41, *f* with ver. 36 (Greek text) is that this method of casting the sacred lot was closely connected with divination by the Ephod (*q.v.*), and was the prerogative of the priests. For this last point the "Blessing of Moses" (Deut. xxxiii.), where the opening words of the Benediction on Levi run thus (text as emended by Ball, following LXX.; *Proc. of Soc. of Bibl. Arch*, 1896): "Give to Levi Thy Thummim, and Thy Urim to the man of Thy favour." For a similar Arabic custom, *cf* G. F. Moore *Ency. Bib.* IV., col. 5236.

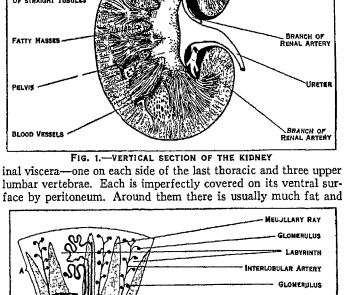
In the post-exilic Priestly Code the Urim and Thummim figure as part of the equipment of the High Priest (*cf.* Ex. xxviii. 30; Lev. viii. 8; Num. xxvii. 21). Here it is stated that they are kept in a square pouch which is worn upon the high priest's breast ("the breastplate of judgment"), and attached to the ephod. Thus the association of the Urim and Thummim with the ephod, is retained.

That Urim and Thummim were not then in use is shown by Neh vii 65 (Ezra ii 63; I Esdras v. 40). Later references (Ecclus xiv. 10, in Josephus and the Talmud) prove that no real tradition survived on the subject. As vocalized in the Massoretic Hebrew text the names="Lights and perfections" But the Greek translators read the former *orim* and connected it with *torah*, "decision"; it would thus mean "doctrine", so Symmachus (*cf.* I. Esd. v. 40).

BIBLIOGRAPHY.—For the older views, *see* Spencer, *De leg Hebr rit. Diss* VII ; and a useful summary by Plumptre in Smith's *Bib Dict.* For modern discussions, *see* the articles "Urim and Thummim" in the Bible Dictionaries, the relevant sections in the treatises on archaeology, and W Muss-Arnolt, "The Urim and Thummim" (*Amer. Journ of Semtic Lang*, 1900). (G. H. B)

URINARY SYSTEM. The urinary system in the fully developed human being consists of (1) the kidneys, (2) the ureters, (3) the urinary bladder, and (4) the urethra.

The Kidneys.—The *kidneys* are two firm, reddish brown organs about 4½in. long, placed obliquely behind the other abdominal viscera—one on each side of the last thoracic and three upper lumbar vertebrae. Each is imperfectly covered on its ventral surface by peritoneum. Around them there is usually much fat and areolar tissue. The degree to which the kidney is fixed in position varies somewhat. In so-called moveable or floating kidney the mobility may give rise to symptoms. The kidney in the foetus is lobulated, but becomes smooth in later years of childhood Each organ has a firm, fibrous capsule, easily stripped off when the kidney is healthy. The inner and ventral margin of each kidney is concave



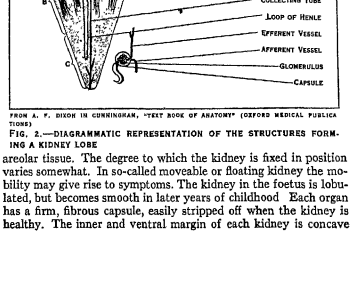


FIG. 1.—VERTICAL SECTION OF THE KIDNEY

FROM A. F. DIXON IN CUNNINGHAM, "TEXT BOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 2.—DIAGRAMMATIC REPRESENTATION OF THE STRUCTURES FORMING A KIDNEY LOBE

(*hilum*) and contains the renal artery and vein and the ureter which is always behind and below the blood vessels. Longitudinally divided from hilum to outer edge, the cut surface is seen to consist of two parts—an outer layer, the cortex, and an inner part, the medulla (fig. 1). The latter consists of a series of eight to sixteen pyramids, whose bases and sides are invested with cortical matter, and whose apices or papillae project into the pelvis of the

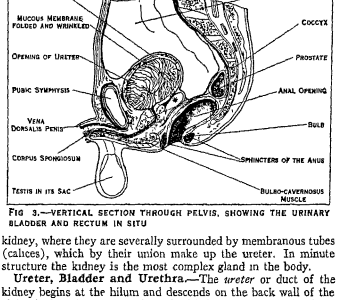

FIG 3.—VERTICAL SECTION THROUGH PELVIS, SHOWING THE URINARY BLADDER AND RECTUM IN SITU

kidney, where they are severally surrounded by membranous tubes (calices), which by their union make up the ureter. In minute structure the kidney is the most complex gland in the body.

Ureter, Bladder and Urethra.—The *ureter* or duct of the kidney begins at the hilum and descends on the back wall of the abdominal cavity to open into the bladder. It is usually about 12in. in length and as thick as a goose quill. At its termination it passes obliquely through the coats of the bladder, so that when the bladder is distended the lumen of its end is closed. The *urinary bladder* is a membranous bag lying in the pelvic cavity directly behind and above the dorsal surface of the pubes. In the foetus and infant, however, the bladder lies in the abdomen, not in the pelvis. During life it is seldom distended so as to hold more than about 10oz. When distended it rises and is applied closely against the back of the ventral abdominal wall. The bladder has a strong wall of unstriped muscle in several layers, which are innervated by branches from the sacral nerves. It has a peculiar epithelial lining of several strata, the superficial cells of which are cubical when the sac is collapsed, but flattened and scale-like when it is distended. At the lower part of the bladder is a triangular space known as the trigone, the angles of which are formed by the openings of the two ureters and the urethra. In this space the mucous membrane is smooth and firmly bound to the subjacent muscle; elsewhere it is thrown into numerous folds when the bladder is empty. The female urethra is 1½in. in length and is comparable only with that part of the male urethra which extends from the bladder to the openings of the seminal ducts (fig. 3). The male urethra is described under REPRODUCTIVE SYSTEM, ANATOMY OF.

Embryology.—The excretory organs are developed as a series of small tubes situated in the intermediate cell mass, the ventral part of which projects to form the Wolffian ridge. Three sets of these tubes appear in succession and occupy the whole length of the body from the cervical to the lumbar region. The most anterior—*pronephros* or *head kidney*—is represented in man by only two or three small tubules on each side which appear as ingrowths from the neighbouring coelom (fig 4). It is probable that these are only mere vestiges. Although the pronephros is rudimentary, the duct which in lower types carries away its excretion is well developed. This is the *Wolffian duct*, which appears in man before the pronephric tubes are formed, and runs longitudinally back in each intermediate cell mass to open into the cloaca (fig. 4). In certain parts of its course it is, at an early date, close to the skin on the dorsal side of the intermediate cell mass, and many embryologists hold that it is originally ectodermal and has sunk into the mesoderm secondarily. Morphologically, this view seems likely.

When the pronephric tubules disappear, which they do early in the embryo's development, the Wolffian duct persists as the drain for another and more important series of tubules (the *mesonephros* or *middle kidney*), formed in the intermediate cell mass behind the pronephros (fig. 4). There is some doubt whether these tubes are strictly homologous and in series with those of the pronephros; they are of later development.

By about the sixth week of intra-uterine life these tubules reach their maximum development and form the *Wolffian body*, which projects into the coelom as the now very definite *Wolffian ridge* and acts as the functional excretory organ of the embryo. When the permanent kidney is formed this organ degenerates; for its ultimate fate *see* REPRODUCTIVE SYSTEM, ANATOMY OF.

The *metanephros* or *hind kidney* begins as a diverticulum from the dorsal side of the Wolffian duct close to its opening into the cloaca (*see* fig 4); this organ occurs about the fourth week of intra-uterine life, and the diverticulum grows forward (cephalad), dorsal to the hind end of the Wolffian body. In doing this it forms a duct—the *metanephric duct* or *ureter*—the cephalic end of which enlarges and divides to form the calices of the kidney. From the calices numerous smaller ducts grow into the mesoderm of the hind (caudal) end of the intermediate cell mass and become the collecting tubes of the kidney. While this is going on another set of tubules, probably in series with the mesonephric tubules, develops independently in the intermediate cell mass and forms the rest of the tubular system of the kidney. Toward these tubules, at one point, branches from the aorta push their way and invaginate each tube, thus forming the Malpighian corpuscles.

By the eighth week the kidney is definitely formed and takes over the excretory work of the mesonephros, which now atrophies.

At first, as has been stated, the ureters open into the Wolffian ducts, but later on each gains a separate opening into the cloaca, and eventually these shift ventrally until they reach their permanent connection with the allantoic bladder.

The *bladder* is developed from that part of the allantois which is nearest the cloaca. At first it is tubular, but after the second month becomes pyriform, the stalk of the pear corresponding to the fibrous *urachus* which reaches the umbilicus.

The *Müllerian ducts* (fig. 4) are formed after the Wolf-

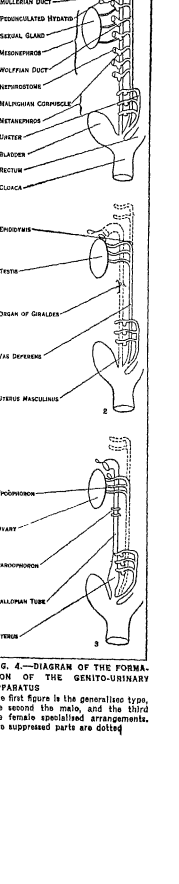

FIG. 4.—DIAGRAM OF THE FORMATION OF THE GENITO-URINARY APPARATUS

The first figure is the generalised type, the second the male, and the third the female specialised arrangements. The suppressed parts are dotted.

fian ducts are fully developed. A ridge appears in the intermediate cell mass ventral to the Wolffian duct, and into the anterior (cephalic) end of this a tubular process of the coelom forces its way backward (caudad) Before reaching the cloaca the two Mullerian ducts coalesce and open between the orifices of the two Wolffian ducts. These ducts form the oviducts, uterus and at least part of the vagina.

Comparative Anatomy.—In the Acrania (Amphioxus) the nephridial tubules are segmental and are only found in the pharyngeal region; each opens into the coelom by several ciliated funnels (nephrostomes) and also into the atrium, which is the exterior of the animal, by an opening called the nephridiopore.

Among the Cyclostomata (lampreys and hags) the pronephros persists throughout life in Bdellostoma and probably in the hag (Myxine), but a Wolffian (archinephric) duct has been evolved so that the tubules no longer open on the surface by nephridiopores. In the Teleostomi (bony and ganoid fish) the pronephros is aborted and the mesonephros is the functional kidney.

In the Elasmobranchii (sharks and rays) the pronephros is more completely and more early aborted than in the last subclass, and the mesonephros is divided into an anterior or genital part (which receives the vasa efferentia in the male from the testis and thus is the first appearance phylogenetically of an epididymis) and a posterior or renal part The Wolffian duct therefore acts both as a vas deferens for the sperm and a ureter for the urine, though in the female it is merely a ureter

The Dipnoi or mudfish are remarkable for having a cloacal caecum which probably functions as an urinary bladder.

In the Amphibia the snake-like forms (Gymnophiona) show a very primitive arrangement of the kidney tubules, each having its nephrostome, Malpighian capsule and short convoluted part leading to the Wolffian duct which acts both as ureter and vas deferens.

In Reptilia the hind kidney or metanephros is developed and takes over all the excretory work; it is usually lobulated, its nephridia are never provided with nephrostomes and its duct (the ureter) opens into the Wolffian duct or vas deferens before reaching the cloaca. Birds resemble reptiles very closely in their urinary system except that there is no bladder and that the ureters and vasa deferentia open independently into the cloaca.

In the Mammalia the bean shape of the kidney is fairly characteristic In foetal life the organ is always lobulated, and this often persists in the adult as in the ox, bear, seal and whale.

URMIA (Urumia), recently renamed Rezaieh, a city in the province of Azerbaijan in Iran, on a plain at an elevation of 4,400 ft., in 37° 34′ N, and 45° 4′ E., 155 mi. around the lake by road via Marand and Khoi from Tabriz. The population before the war was roughly estimated at 45,000, being mainly Turkish, with Armenian and Assyrian (Nestorian) minorities. It is clean with broader and less oriental-looking streets than in most Iranian towns; and the bazaars, a maze of domed and brick-vaulted corridors The plain of Urmia is fertile. By means of irrigation, cultivation especially of fruits and tobacco reached a high standard. Large amounts of raisins, dried apricots and tobacco are exported to Russia.

In World War I there was a wholesale exodus of Christians—said to have reached 59,000—in July 1918, during the Turkish advance after the Russian debacle; and, in the same year, there were massacres by the Turks and Kurds of two-thirds of those who remained. In 1919, the remnant of 600 Christians was transferred to Tabriz Some survivors were repatriated by the Iranian government, and by loans for the repair of buildings and the purchase of seed, oxen and implements, agriculture has been fully restored.

URMIA (URUMIA), LAKE OF, in northwestern Iran, between 37° 10′ and 38° 20′ N. and between 45° 10′ and 46° E., which takes its name (Pers. *Deryacheh i Urmua,* Turk. *Urmi gol*) from the town of Urmia, situated near its western shore, but is also known as the Deryacheh i Shahi and Shahi göl. The limits of the lake vary much, the length (north to south) from 80 to 90 mi, the width (east to west) from 30 to 45, being greater in the season of high water in spring when the snows melt.

The mean depth of the lake is 15 to 16 ft., and its greatest depth probably does not exceed 50 feet. The lake has in recent years exhibited extraordinary changes of level, either due to a movement of the earth's crust or merely to an increase of rainfall as compared with evaporation. De Morgan gives an area of 4,000 and 6,000 sq.km. (1,544 and 2,317 sq.mi.) for low and high water respectively.

In the south is a cluster of about 50 rocky islands, the largest of which, Koyun daghi, *i.e.,* "Sheep-mountain," is 3 to 4 mi. long and has a spring of sweet water near which a few people graze their goats and sheep.

All the other islands are uninhabited. The lake is about three-fifths as salt as the Dead sea—far too salt to permit of any life, except of lower organisms.

By the U.S.S.R treaty with Iran, of 1921, the railway from Tabriz to Julfa and branch line from Sofian to Lake Urmia and all the properties pertaining to navigation on the lake—formerly a Russian concession—were gratuitously transferred to Iran. From the port of Sharaf-Khaneh on the eastern shore of the lake a fleet of motor boats of 20–160 h.p. is operated in conjunction with the railway. The service is weekly. The lake is also navigated by clumsy craft with round bows and flat sterns carrying enormous sails. (*See* Urmia)

UROLOGY. The branch of medicine—chiefly surgical—that deals with diseases of the genito-urinary organs. Recent progress in urology has been due largely to improvements in the cystoscope, advances in radiology, use of diathermy and close co-operation between urologists, bacteriologists, and bio-chemists.

Endovesical instruments are now available from the simplest cystoscope, consisting of a telescope within an irrigating sheath, to complicated instruments with which lesions can be treated surgically under direct vision instead of by an open operation

Similarly, advances in radiology have led to the detection of calculi hitherto regarded as transparent to the rays, and to stereoscopic radiograms indispensable for locating a suspicious shadow in the neighbourhood of the kidney or ureter. Pyelography also gives information concerning the size and shape of the renal pelvis and calices.

A skiagram is taken after a fluid opaque to the X-rays (*e.g.,* sodium iodide or lipiodol) has been introduced into the renal pelvis by means of a ureteric catheter. It is of great value in diagnosing early dilation of the kidney, silent hydronephrosis, polycystic kidney, malformation of the pelvis and renal tumours encroaching on the pelvis; in localising shadows in the renal area such as calcified mesenteric glands and gall stones, and in differentiating between abdominal and renal tumours.

By similar means, silhouettes of the bladder or male urethra can be obtained, though in the latter instance they are not indispensable, for the canal can be examined easily and thoroughly with a urethroscope.

Perirenal inflation with CO_2 was introduced by Carelli of Buenos Aires and in radiographs shows clearly alterations in shape, size and density, therefore being useful in such conditions as early hydronephrosis, polycystic kidneys, tuberculosis, tumours and stones not dense enough to show by ordinary radiography; but its greatest value lies in giving a clear and distinct radiogram of the suprarenal capsule.

Diathermy.—Diathermy (*see* ELECTROTHERAPY) acts by virtue of the heat generated in the tissues by the resistance they offer to the passage of an electric current. For this purpose a very strong current must be used, deprived of its stimulating and electrolytic properties by alternations of not less than 500,000 per second

The only sensation produced by a current of such high frequency is one of heat ranging, according to the strength of the current, from a pleasing warmth to a temperature high enough to char the tissues for a distance of about 1 cm from the electrode All degrees of diathermy are used for diseases of the genito-urinary system, the lower temperatures for testicular neuralgia and epididymo-orchitis, chronic urethritis and prostatitis, and benign enlargement of the prostate when a radical operation is inadvisable. Destructive diathermy is now the method of choice in the treatment of certain forms of papilloma of the bladder and urethra, and in the median bar type of prostatic obstruction. It has been used with moderate success for carcinoma of the prostate.

Use of Radium.—Radium (*q.v.*) has been used extensively for carcinoma of the prostate and bladder It is applied in the form of needles and emanation tubes or seeds implanted directly into the growth, but has not yet emerged from the experimental stage Caution is required in its use, for large doses produce great irritation and may be followed by excessive infiltrations of the bladder neck Again, emanation tubes placed too close to the pouch of Douglas have caused peritonitis and death. In view of these disadvantages and the discouraging results they have encountered many urologists are now averse to using it at all.

Urinary Antiseptics.—Both mercurochrome and hexyl-resorcinol are powerful antiseptics, and though not "ideal" are valuable additions to the comparatively few powerful bactericides which can be administered with safety. Mercurochrome can be used either locally or intravenously. In cases of chronic cystitis, usually due to the colon bacillus, instillation of a watery solution (0·2–1·0%) sometimes has a remarkable effect. In pyogenic coccal infections the results are not so striking. In pyelitis, irrigation with mercurochrome is not so irritating as with silver nitrate. Instillations appear to be particularly valuable for chronic posterior urethritis, especially when complicated by prostatitis and vesiculitis. When given intravenously in doses of from 1 to 5 mg. per kg of body weight results have been most encouraging, especially in acute coccal and bacillary infections of the genito-urinary tract associated with pyrexia Chronic afebrile colon bacilluria, on the other hand, does not always respond so readily to this treatment. In rare cases, pronounced febrile and gastro-intestinal reactions follow the injection but these usually subside in 24 hours. The danger to the kidneys of such a powerful mercurial compound must never be overlooked, but Young (Baltimore) considers it may be used intravenously without fear of injury.

Hexyl-resorcinol $[C_6H_3(OH)_2C_6H_{13}]$ is a synthetic compound first described by Leonard. Possessing forty-five times the germicidal power of phenol, it conforms experimentally to the qualifications necessary for an ideal urinary antiseptic in that it is chemically stable, non-toxic, non-irritating to the urinary tract, has an antiseptic and bactericidal action in high dilution in urine of any reaction, and is eliminated in high percentage by the kidneys. On the other hand, it can only exert its germicidal properties on tissues with which the urine comes in contact, and therefore infections of the renal parenchyma and submucous tissues of the urinary tract are not affected by it. If taken on an empty stomach the drug may cause griping or catharsis. Infections due to pyogenic cocci appear to yield to the drug with remarkable rapidity. *B. coli* infections of the urinary mucosa with a low bacterial count can be cured with hexyl-resorcinol, but when the count is high and the sub-mucous tissues are infected, prolonged treatment combined with appropriate local treatment is necessary. When administered prophylactically two days before, and daily after operations on the bladder, the wounds remain healthy and healing is accelerated

Tests of Renal Function.—Tests for estimating the function of one or both kidneys are now employed regularly. Though not conclusive, they are capable of giving a warning which should be heeded, particularly in operations on the urinary tract. Thus in prostatectomy they serve to determine a one- or two-stage operation, and since they have been adopted as a routine the mortality from uraemia has become almost negligible. The chief tests in use in England are. (1) The urea concentration test (Maclean and de Wesselow), (2) estimation of blood urea; (3) colour tests. The technique of applying these tests can be found in text-books

The range of normality of the blood urea is so great that this test alone is of little value unless the urea retention is above 50 mg per 100 cu cm of blood, but when combined with the urea concentration test it gives an excellent indication of the renal efficiency. In some clinics on the Continent great reliance is placed on the elimination of creatinin and chlorides as tests of renal efficiency. The dyes chiefly employed for colour tests are indigo-carmine and phenolsulphonaphthalein. Indigo-carmine can be employed during a cystoscopy and gives a good indication of the function of one kidney without the use of a ureteric catheter (chromocystoscopy). A 0·4% solution injected either intravenously (5 c c) or intramuscularly (20 c.c.) should tinge the urine of a healthy kidney in five minutes. Phenolsulphonaphthalein is excreted solely by the kidneys and so differs from indigo-carmine, which is only partly excreted by the kidneys. In America it is used almost exclusively, but in England it has not been popular owing to the somewhat elaborate technique required and to the difficulty, since the War, of obtaining a reliable preparation of the dye The test is very reliable provided the pure compound is used.

The capacity or otherwise of a patient to resist the spread of sepsis to the upper urinary tract after an operation, such as prostatectomy, is a factor which may upset the calculations of both surgeon and bio-chemist. MacAdam and Shiskin have found that the *cholesterol content* of the blood gives a fair indication of the power of resistance. The average in a series of healthy adults under 50 years of age was found to be 0·16%. Above 50 years it ranges between 0·13% and 0·19%. Practical experience led these workers to conclude that in prostatic obstruction a blood-cholesterol below 0·13% indicates such a lowered resistance to the spread of sepsis as to constitute a bad operative risk Cases with a high blood-urea and a normal blood-cholesterol all recovered from a two-stage prostatectomy, but out of eight cases with a high blood-urea and a low blood-cholesterol all died save one

The Kidney.—Dudgeon and others have pointed out that the combination of pus cells and a pure culture of staphylococcus albus in the urine of one kidney is almost pathognomonic of a stone in that kidney. With certain reservations all cases of renal calculus are now subjected to operation, for the stone, whether causing symptoms or not, slowly but surely injures the kidney and often determines a serious bacterial infection. Small stones are more dangerous than large ones, for they may lodge in the ureter and cause hydronephrosis, anuria and so on.

The problem of bilateral lithiasis is a difficult one, but on the whole urologists advocate operation on the healthiest kidney first, as there is always the possibility that nephrectomy may be necessary on the side which is more grossly affected. Pyelolithotomy is now performed in preference to nephrolithotomy whenever possible

Decapsulation of the kidney for nephritis has been performed on many occasions with varying success, but is viewed with increasing favour. The benefit obtained is probably due to the mechanical relief of renal tension, and this certainly explains the immediate improvement following unilateral decapsulation in eclamptic uraemia. The indications for this operation are uraemia, anuria, oedema, excessive albuminuria and obstinate haematuria. Contra-indications are age, heart diseases and extensive cardiovascular changes.

Renal Tuberculosis.—Investigations by Braasch in the Mayo clinic have disproved the common opinion that renal tuberculosis is usually primarily unilateral In seven out of 22 apparently unilateral cases, the urine from the supposed healthy kidney was proved to contain tubercle bacilli by animal inoculation, a fact which goes far to explain the comparatively heavy mortality in the first few years after nephrectomy. Continental writers estimate

that in life the infection is bilateral in about 15% of cases, whereas in the post-mortem room it is as high as 65%. This fully bears out the experience that spontaneous cure is extremely rare and that the only rational treatment of unilateral tuberculosis is early nephrectomy. In bilateral infections, Ekehorn advocates and practises removal of that kidney which is found by inspection to be the most diseased, or is thought to be the cause of pyrexia and distressing bladder symptoms. In 20 cases reported by him the results were good enough to justify the operation. The treatment of the tuberculous ureter is still under discussion, most workers considering that it heals naturally after the diseased kidney has been removed, while others advocate a primary nephro-ureterectomy to prevent infection of the lower urinary tract by the diseased ureter. All are now in favour of a post-operative course of tuberculin.

Movable Kidney.—Operations for nephroptosis are decreasing in number year by year, for surgeons have now realised that the condition is commonly associated with Glenard's disease and with such general symptoms as headache, gastric discomfort, neurasthenia and ptoses of various kinds, for which fixation of the kidney gives no relief whatever. Nephropexy is now reserved chiefly for cases of intermittent hydronephrosis, haematuria, casts and albuminuria, and for uncomplicated renal pain relieved absolutely by rest in the horizontal position

Ureteral Calculus.—In the case of small stones impacted in the ureter most urologists favour removal by manipulative and other methods rather than by ureterolithotomy. The chief methods employed are: (i) dilation of the ureter combined with instillation of sterile liquid paraffin, subcutaneous injection of atropine, and forced diuresis with Contrexéville water; (ii) intra-ureteral instillation of 5 cu cm. of a 2% solution of papaverine sulphate, selected for its analgesic and antispasmodic properties; (iii) dilation of the ureter by diathermy, and (iv.) division of the ureteric meatus with scissors through a cystoscope.

Severe reactions after cystoscopic manipulations, and irregular stones greater than 1 cm. in diameter are indications for ureterolithotomy. The pelvic portion of the ureter is now always exposed extraperitoneally, either through a paramedian subumbilical incision or by Kidd's inguinal operation.

Bladder.—The ureter may be implanted into another part of the bladder, either for stricture of its extramural portion or after partial cystectomy for growths involving the ureteric orifice. For inoperable bladder growths and for extrophy of the bladder, Coffey has devised a method of simultaneous transplantation of both ureters into the pelvic colon, which does not obstruct the ureters or disturb kidney function.

The bacteriology of cystitis and pyelocystitis has received much attention from bacteriologists. The most important recent communications on this subject are by Dudgeon, Wordley and Bawtree. These workers have isolated from different cases:—

(1) A special group of haemolytic bacilli, strongly resembling but not identical with the paratyphoid bacillus; (2) the colon bacillus; (3) Proteus.

Improvements in the cystoscope have led to earlier recognition of diverticula. Swift Joly reviews the whole subject and discusses the relative value of the different operations. He also points out that accompanying prostatic or urethral obstruction should be treated at the same time whenever possible

Papilloma.—These tumours are now treated by fulguration through a cystoscope whenever possible, and in many instances can be destroyed completely at one sitting and under local anaesthesia. When the papilloma is sessile and diathermy can only be applied to the surface nearest the cystoscope, several treatments at intervals of a week or ten days may be required, a portion of the growth being destroyed at each sitting. Subsequently a cystoscopic examination should be made at intervals of three to six months for at least three years, so that fresh growths can be kept in check. Open operation by the suprapubic route is reserved for large growths, especially if sessile and for those involving the ureteric orifice. In some cases the tumour can be destroyed by diathermy with a large electrode, in others a partial cystectomy, with or without transplantation of the ureter, is necessary. Attention has been called to the danger of "graft-recurrences" in the abdominal wall after removal of papillomata by the suprapubic route, and Maybury and Dyke have reported a case in which three successive implants grew in the abdominal wall. The primary vesical growth was benign but the recurrent implants became progressively malignant. Carcinoma should be excised whenever possible, for as yet the results of treatment with imbedded radium is disappointing and uncertain. In the flat ulcerating form of carcinoma, peculiar to the aged, a fair measure of comfort and relief can be obtained from deep X-ray therapy.

The Prostate.—For chronic inflammatory lesions of the prostate and seminal vesicles diathermy is valuable and acts, not only on the gland itself, but also on the arthritic and other complications so frequently associated with gonorrheal prostatitis and vesiculitis. In cases of enlarged prostate where operation is impossible owing to age, cardiovascular changes, advanced renal disease, etc., a fair measure of relief can be obtained by medical diathermy or by deep X-ray therapy. In all other cases prostatectomy is undoubtedly the correct procedure. The type of enlargement most suitable for operation is that due to chronic lobular prostatitis with pronounced adenomata; the second type, chronic interstitial prostatitis or fibrous prostate, presents many difficulties to the operator but should be removed whenever possible, as it causes a severer degree of obstruction and consequent impairment of the renal function than the adenomatous variety. Before deciding on an operation the chemical tests of renal efficiency should be carried out, for the type of operation selected will depend almost entirely on these tests. Careful preliminary treatment, often lasting several weeks, is nearly as important as the operation itself.

After much discussion, the majority of urologists have decided in favour of the suprapubic operation in one or two stages. The two-stage operation has reduced the mortality from uraemia to a negligible quantity and is indicated in all cases with renal deficiency, severe cystitis, retention, or four or more ounces of residual urine. The Thomson-Walker operation is undoubtedly an improvement on the somewhat crude but remarkably effective operation practised by Freyer. It takes longer but eliminates the risk of post-operative stricture. The perineal operation, performed almost exclusively by Young of Baltimore, is in England reserved for carcinoma and for the fibrous type of prostate. Here the advantages of control of haemorrhage and perfect drainage are outweighed by the dangers of pelvic cellulitis, perineal fistula and incontinence of urine.

In about 25% of patients with symptoms of prostatic obstruction but without palpable enlargement of the prostate, a careful cystoscopic examination reveals the presence of a ridge of hypertrophied tissue, either on the posterior lip of the prostate overhanging the internal meatus, or projecting upwards from the floor of the prostatic urethra and constituting the so-called median bar. For the relief of this type of obstruction H. Young invented his well-known punch, later improved by Kenneth Walker, by adapting it for diathermy. (*See* ELECTROTHERAPY.)

Hitherto, treatment of prostatic carcinoma by radium has been so unsatisfactory that many surgeons have ceased to use it. Diathermy has been more or less successful in conferring relief, but the results can hardly be described as brilliant. Whenever possible, Young's perineal resection appears to be the most satisfactory procedure; failing this, excellent results have been sometimes obtained from deep X-ray therapy.

The Testis.—Steinach of Vienna performed vasoligation in *senile* rats with a view to increasing the internal secretion of their testes and thereby stimulating their failing energies. For two to four weeks after bilateral division of the vas between ligatures no appreciable change was noticeable. The rats then began to show a return of sexual excitement and vigour, in some instances equalling that of young males. This was followed in rapid succession by a return of pugnacity, increase in muscular energy and a copious growth of fur The change lasted for about six months, when the animal gradually lost his youthful appearance and powers and became senile again, eventually dying within a few weeks of the onset of the change. Steinach found that the operation induced degeneration of the seminal epithelium (later followed by regeneration) and an increase in the interstitial tissue In man the operation has been attended by very variable results. The

greatest successes appear to have occurred in cases of premature old age; when performed for impotence alone it is not so satisfactory, and is quite useless if the testis be already atrophied Some cases of arteriosclerosis have been greatly benefited by it.

Testicular Grafts (*see* REJUVENATION) —Grafts from lower animals have been employed for many years with more or less similar results, viz , improvement shortly after implantation, followed by atrophy and absorption of the graft, and a return on the part of the patient to the original condition. Voronoff in 1920 used testes of anthropoid apes and found that they survived for three years or longer, and that the initial improvement in the patient's condition was maintained. Kenneth Walker has on several occasions employed a healthy human ectopic testis. He concludes that the life of a hetero-graft is not longer than two years. that absorption of the graft does not necessarily imply a return of the patient to his former condition, and that permanent improvement is probably due to increased growth in other endocrine tissues stimulated into activity by the graft

Tuberculous Epididymitis.—When this disease is advanced castration is indicated, but when it is localised to the globus major or minor epididymectomy is now regarded as the correct procedure. The full extent of the disease must always be determined with care

The Urethra.—The great improvement in urethroscopes has simplified the diagnosis and treatment of urethral conditions. With the Joly type of posterior urethroscope, diathermy can be applied where formerly a serious cutting operation was necessary. There is now an increasing tendency to revert to former methods and to treat stricture of the urethra by gradual dilatation with metal sounds or gum elastic bougies, urethrotomy being reserved for resilient and cartilaginous strictures and those complicated by fistulae. If contraction recurs after internal urethrotomy many surgeons advocate excision of the stricture and axial anastomosis. When a large amount of cicatricial tissue has been excised, the gap has been successfully bridged in one case by implantation of the patient's appendix, and in another by a child's prepuce fashioned into a canal around a catheter.

UROTROPIN, known also as uritone, a chemical substance (hexamethylenetetramine) formed by the action of ammonia on formaldehyde, used in medicine. It consists of colourless granular crystals freely soluble in water and having an alkaline reaction. Urotropin is among the most powerful of urinary antiseptics It is used to render the urine acid in cases where it is alkaline, loaded with phosphates or purulent, as in cystitis. It is slightly diuretic. Experimentally it has been shown to have a solvent action on uric acid, but its action in this direction in the body requires confirmation. Urotropin is valuable in sterilizing the urine of "typhoid carriers." (*See* CARRIERS) Analogous preparations are cystamine, helmitol and hetralin Chinotropin is urotropin quinate, and borovertin is urotropin triborate.

URQUHART, DAVID (1805–1877), British diplomatist, was born at Braelangwell, Cromarty. He was educated in France, Switzerland and Spain, and at St. John's college, Oxford He served (1827–28) in the Greek navy in the War of Independence, being severely wounded In 1830 his reports on the new Greek frontier, as determined by the protocol of March 22, 1829, were of great service to the British Government. In Nov. 1831 he was appointed attaché to Sir Stratford Canning (Lord Stratford de Redclyffe, *q.v.*) on his mission to the sultan for the final delimitation of the frontiers of Turkey and Greece In 1833 he went on a secret mission to Turkey in the interests of British trade, but he was recalled by Palmerston on account of his indiscreet advocacy of British intervention on behalf of the sultan against Mehemet Ali. In 1835 he founded the *Portfolio*, printing in the first issue a series of Russian State papers, which made a profound impression As M.P. for Stafford (1847–52) he vigorously opposed Palmerston's foreign policy. He protested against the action of England in the Crimean War, advocating Turkish autonomy. He organized "foreign affairs committees" (known as "Urquhartite") throughout the country, in opposition to the Government, and in 1855 founded the *Free Press* (renamed in 1866 the *Diplomatic Review*) to which Karl Marx was a contributor His health obliged him to retire to Montreux in 1864, and he died in Naples on May 16, 1877.

He published *Turkey and its Resources* (1833); and *England, France, Russia and Turkey* (1833), both violently anti-Russian; and *The Lebanon* (1860).

URQUHART or URCHARD, **SIR THOMAS** (1611–1660), Scottish translator of Rabelais, was the son of Sir Thomas Urquhart of Cromarty, and of Christian, daughter of the fourth Lord Elphinstone. After part of his estate had been alienated he received a "letter of protection" from his creditors from Charles I. in 1637. He took part in the "Trot of Turriff" in 1639, and was knighted in 1641. He then published his *Epigrams* In 1645, he produced a tract called *Trissotetras*, a treatise on logarithms, adjusted to a kind of memoria technica, like that of the scholastic logic. In 1649 he was proclaimed a traitor for taking part in the rising at Inverness At Worcester, he was wounded and taken prisoner. His mss. were almost wholly destroyed. Urquhart was released by Cromwell's orders in 1651 He published during 1652 and 1653 three tracts with quaint titles and quainter contents, the last being on a universal language.

The *Translation of Rabelais* (Books I and II.), which Urquhart produced in 1653, is a masterpiece of translation. Though not a close rendering, it reproduces the spirit of the original The translation was reprinted in 1664, and in 1693 that of the Third Book was added It is said the Urquhart sought refuge during the Commonwealth, like other cavaliers, on the continent, and died (1660) of a fit of laughing, brought on by joy over Restoration

URSA MAJOR ("The Great Bear"), in astronomy, a constellation of the northern hemisphere, supposed to be referred to in the Old Testament (Job ix. 9, xxxviii. 22), and mentioned by Homer, "Αρκτον θ', ἣν καὶ ἅμαξαν ἐπίκλησιν καλέουσιν (*Il.* 18. 487). The Greeks identified this constellation with the nymph Callisto (*q.v.*) placed in the heavens by Zeus in the form of a bear together with her son Arcas as "bear-warder," or Arcturus (*q.v.*); they named it Arctos, the she-bear, Helice, from its turning round the pole-star. The Romans knew the constellation as *Arctos* or *Ursa;* the Arabians termed the quadrilateral formed by the four stars α, β, γ, δ, *Na'sh*, a bier, whence it is sometimes known as *Feretrum majus*. The Arabic name should probably be identified with the Hebrew name *'Ash* and *'Ayish* in the book of Job (*see* G. Schiaparelli, *Astronomy in the Old Testament*, 1905). Ptolemy catalogues eight stars. Of these, the seven brightest (six stars, α, β, γ, ε, ζ and η are of the 2nd magnitude, and δ of the third magnitude) constitute one of the most characteristic figures in the northern sky; they have received various names—Septentriones, the wagon, plough, dipper and Charles's wain (a corruption of "churl's wain," or peasant's cart). With the Hindus these seven stars represented the seven Rishis. The stars α and β are called the "pointers," since they point to the pole-star Five stars of the Plough form an associated group with common proper motion; but α (the upper pointer) and η (the last star of the tail) have no connection with the others. Stars in other parts of the sky have been found to belong to the same cluster; in particular Sirius is a stray member of it

URSA MINOR ("The Little Bear"), in astronomy, a constellation of the northern hemisphere, mentioned by Thales (7th century B.C.). By the Greeks it was sometimes named *Cynosura* (Gr. κυνός, dog's; οὐρά tail), alleging this to be one of the dogs of

Callisto, who became *Ursa major*. The Phoenicians named it Phoenice, or the Phoenician constellation, possibly in allusion to the fact that the brightest star, Polaris, being situated very close to the north pole, is of incalculable service to navigators Polaris, a second magnitude star, was in 1937 distant 1° 2′ from the celestial pole It is a Cepheid variable with very small light-range.

URSINS, MARIE ANNE DE LA TRÉMOILLE, PRINCESSE DES (1642–1722), lady of the Spanish court, daughter of the duke of Nourmontier and Renée Julie Aubri. After the death of her second husband, Flavio Orsini, duke of Bracciano, she assumed the title of Princess des Ursins, a corruption of Orsini, and for her unofficial services in securing Neapolitans and Spaniards of rank at Rome as French partisans in view of the approaching death of Charles II. of Spain, she was rewarded in 1699 by a pension When Philip, duke of Anjou, grandson of the French king was declared heir by the will of Charles II the princess took an active part in arranging his marriage with a daughter of the duke of Savoy Appointed *Camarera Mayor* by quiet diplomacy and the help of Madame de Maintenon, she accompanied the young queen to Spain in 1701. Till 1714 she was the most powerful person in the country She was expected to look after French interests in the palace, and to manage the Spanish nobles. But she wisely held that the young king should rely on his Spanish subjects and was in frequent conflict with the French ambassadors. Recalled in 1704, she still had the support of Madame de Maintenon, and her own tact placated Louis XIV. In 1705 she returned to Spain, with practically the power to name her own ministry. During the war of the Spanish Succession she was the real head of the Bourbon party. She was so far from offending the nation, that when Louis XIV. threatened in 1709 to desert his grandson, she dismissed all Frenchmen from the court On the death of the queen, acting by advice of Alberoni, she arranged a marriage for the king with Elizabeth Farnese of Parma She was rudely disillusioned in her hopes of governing the new queen as she had done the old Driven from Elizabeth's presence with insult, at Quadraque, whither she had gone to meet her, she was sent out of Spain without being allowed to change her court dress. After a short stay in France, Madame des Ursins went to Rome, where she died Dec. 5, 1722

See F. Combes, *La Princesse des Ursins* . . (1858); *Lettres inédites de Mme de Maintenon et de . . . la Princesse des Ursins* (1826; Eng. trans., 1827); *Lettres inédites de la princesse des Ursins* (1859), C. Hill, *Story of the Princess des Ursins in Spain* (1905).

URSULA, ST., and her companions, virgins and martyrs, are commemorated on Oct. 21. The *Breviary* gives no legend; but in current works, such as Butler's *Lives of the Saints*, it is to the effect that "these holy martyrs seem . . . to have met a glorious death in defence of their virginity from the army of the Huns . . . They came originally from Britain, and Ursula was the conductor and encourager of the holy troop." The scene of the martyrdom is placed near the lower Rhine.

The date has been assigned by different writers to 238, *c.* 283 and *c.* 451. The story, however, is unknown both to Jerome and to Gregory of Tours—and this though the latter gives a somewhat detailed description of the Cologne church dedicated to that Theban legion with which the tradition of the martyred virgins was very early associated. The story of their fate is not entered under Oct. 21, in the martyrology of Bede (*ob c.* 735), of Ado (*c.* 858), of Usuard (*ante* 877), Notker Balbulus (896) or Hrabanus Maurus (845); but a 9th-century life of St Cunibert (*ob.* 663) associates a prominent incident in the life of this saint with the basilica of the sacred virgins at Cologne (Surius vi sant 275, ed 1575). Not only does Archbishop Wichfrid attest a grant to the church of the sacred virgins outside the walls of Cologne (in 927), but he was a large donor in his own person. Still earlier a Cologne martyrology, written, as Binterim (who edited it in 1824) argues, between 889 and 891, has the following entry under October 21: "xi. virg. Ursule Sencie Gregorie Pinose Marthe Saule Britule Satnine Rabacie Saturie Paladie." Much shorter entries are found in two of the old martyrologies printed in Migne (cxxxviii 1207, 1275). A more definite allusion to the legend may be found (*c.* 850) in Wandelbert of Prüm's metrical martyrology (Oct. 21):

> Tunc numerosa simul Rheni per littora fulgent
> Christo virgines erecta tropaea manipla
> Agrippinae urbs, quarum furor impius olim
> Millia mactavit ductricibus inclyta sanctis.

The full legend first makes its appearance in a festival discourse (*sermo*) for Oct 21, written, as internal evidence seems to show, between 731 and 839 This *sermo* does not mention St. Ursula, but makes Pinnosa or Vinnosa the leader of these spiritual "amazons," who, to avoid Maximian's persecution, left their island home of Britain, following their bridegroom Christ towards that East whence their faith had come a hundred years before The concurrent traditions of Britain, Batavia, etc, the Netherlands (where many chapels still preserved their memory), and Cologne are called in evidence to prove the same origin. The legend was already very old and the festival "nobis omni tempore celeberrima"; but, as all written documents had disappeared since the burning of the early church erected over the sacred bones, the preacher could only appeal to the continuous and careful memory of the society to which he belonged (*nostrates*)

Two or three centuries later the *Passio XI. MM. SS Virginum*, based apparently on the revelations made to Helentrude, a nun of Heerse near Paderborn, gives a wonderful increase of detail The narrative in its present form may date somewhere between 900 and 1100, while Helentrude apparently flourished before 1050. According to her account, the son of a powerful pagan king demands in marriage Ursula, the beautiful daughter of Deonotus, a king "in partibus Britannıae" Ursula is warned by a dream to demand a respite of three years, during which time her companions are to be 11,000 virgins collected from both kingdoms. After vigorous exercise in all kinds of manly sports, to the admiration of the populace, they are carried off by a sudden breeze in eleven triremes to Thiel on the Waal in Gelderland Thence they sail up the Rhine by way of Cologne to Basel, at which place they make fast their vessels and proceed on foot to Rome Returning, they re-enter their ships at Basel, but are slaughtered by the Huns when they reach Cologne Their relics are then collected and buried "sicut hodie illic est cernere," In a spot where "to this day" no manner sepulture is permitted.

The legend of Cologne grew to further dimensions with the revelations of St Elizabeth of Schonau in the 12th century, motived apparently by the opening up of an old Roman burial ground in Cologne It advanced still further with Hermann Joseph, a Praemonstratensian canon of Steinfeld in 1183, who explained the presence of the bones of little children among those of the sacred virgins

See H. Crombach, *Vita et Martyrium S Ursulae* (Cologne, 1647), and the Bollandist *Acta Sanctorum*, 21st October, where the story fills 230 folio pages. The rationalization of the story is to be found in Oscar Schade, *Die Sage von der heiligen Ursula* (Hanover, 1854), of which there is a short *résumé* in S. Baring-Gould's *Lives of the Saints* See also S Baring-Gould, *Popular Myths of the Middle Ages*; A. G. Stein, *Die Heilige Ursula* (Cologne, 1879). The credibility of some of the details was doubted as early as the 13th century by Jacobus de Voragine in the *Legenda aurea*. (T. A A.; A. J. G.)

URSULINES, a religious order founded at Brescia by Angela Merici (1470–1540) in November 1535, primarily for the education of girls and the care of the sick and needy. It was approved in 1544 by Paul III., and in 1572 Gregory XIII. declared it a religious order under the rule of St. Augustine. In the following century it was encouraged by St Francis of Sales and the Ursulines in Canada did valuable work among the French, the Indians and half-breeds. About 1700, the order embraced some 20 congregations, with 350 convents and from 15,000 to 20,000 nuns.

URTICACEAE (nettle family), a family of flowering plants belonging to the order Urticales, which order includes also Ulmaceae (elm family), Moraceae (mulberry, fig, etc) and Cannabaceae (hemp and hop). It contains 41 genera, with about 480 species, mainly tropical, though several species such as the common stinging nettle (*Urtica dioica*) are widely distributed and occur in large numbers in temperate climates. Two genera are represented in the British Isles, *Urtica* (*see* NETTLE) and *Parietaria* (pellitory, *q.v.*). In addition to *Urtica* and *Parietaria*, four other genera,—*Boehmeria*, *Hesperocnide*, *Laportea* and *Pilea*, are represented in North America, with some 15 native species.

The plants are generally herbs or somewhat shrubby, rarely, as in some tropical genera, forming a bush or tree. The simple, often serrated, leaves have sometimes an alternate sometimes an opposite arrangement and are usually stipulate—exstipulate in *Parietaria*. Stinging hairs often occur on the stem and leaves The bast-fibres of the stem are generally long and firmly attached end to end, and hence of great value for textile use. Thus in ramie (*q.v.*) (*Boehmeria utves*) a single fibre may reach nearly 9 in. in length, and in stinging nettle as much as 3 in *Maoutia* and *Urtica* have also been used as sources of fibre The small inconspicuous regular flowers are arranged in definite (cymose) inflorescences often crowded into head-like clusters. They are unisexual and monoecious or dioecious. The four or five green perianth leaves (or sepals) are free or more or less united; the male flowers contain as many stamens, opposite the sepals. The flowers are adapted for wind-pollination. The female flower contains one carpel bearing one style with a brush-like stigma and containing a single erect ovule. The fruit is dry and one-seeded; it is often enclosed within the persistent perianth The family is divided, according to Engler, into two main classes: (1) the *Urereae* with stinging hairs, including the genera *Urtica, Urera, Laportea*, and (2) others, which are without stinging hairs.

COMMON NETTLE (URTICA DIOICA)

URTICARIA, popularly known as nettlerash or "hives," is characterized by the appearance on the skin of slightly raised red or white patches, varying in shape and size, termed wheals, which develop suddenly, persist for a few hours, and then fade spontaneously and completely. The eruption is invariably accompanied by sensations of itching or burning which may be very pronounced. It is customary to distinguish between an acute and a chronic variety of urticaria. The former is marked by its abrupt onset, the profuse and extensive character of the eruption, and in many cases by the general symptoms which accompany the rash, such as fever, diarrhoea and vomiting. It is often caused by tainted food, and the whole attack is usually limited to a few hours or a few days. In chronic urticaria the eruption is either continuously present over periods of months or years, or is developed in bouts with intervals of comparative or absolute freedom. The onset as a rule is insidious, and the general health is little disturbed unless the degree of itching is sufficient to interfere with sleep or repose.

Nettlerash is now generally held to represent a symptom rather than a genuine disease, for it may be provoked by a great many and very different agents acting externally (nettles, jellyfish), or internally. The theory of sensitization has a special application in urticaria. For example different kinds of foods are capable of causing urticaria under special conditions. A certain individual suddenly becomes unduly "sensitive" to some article of diet which has, up to this point, been eaten without harm, while a second individual develops "hypersensitiveness" to a completely different type of food, a third to something different again, and so on. This acquired condition is specific, that is to say the individual who is "sensitized" only reacts to what is now his own harmful substance (*see* ANAPHYLAXIS) The human tissues can also become "sensitized" to many other agents besides food, such as the poisons liberated from collections of germs in the teeth, tonsils, bowel and other regions of the body (focal infection). In other cases a second injection of horse-serum (diphtheria or tetanus anti-toxin), if given at a sufficient interval of time after the first will sometimes cause urticaria and anaphylactic shock. The mechanism of the reaction is similar in all these cases and the same degree of specificity is observed. The theory of sensitization does not cover every case as, for example, where the eruption is related to an emotional crisis.

(H. MACC.)

URUGUAIANA, a city and river port of Rio Grande do Sul, Brazil, on the Uruguay river. Pop. of the *município* (1950), 49,785. The upper Uruguay is navigable from the Quaraí to the town of Santo Tomé. Opposite Uruguaiana is the Argentine town of Restauración, or Paso de los Libres. The river is 2 mi. wide at this point, and 154 ft. above sea-level. Uruguaiana is situated on a low hill rising gently from the riverside and its low houses are surrounded by orange groves. Uruguaiana was captured by a Paraguayan force Aug. 5, 1865, and recaptured without a fight by the allied forces on Sept 18.

URUGUAY (officially the República Oriental del Uruguay, and still locally called the *Banda Oriental*, the "Eastern Shore" of the Uruguay river), the smallest independent state in South America. It lies between Brazil on the north and the estuary of the Río de la Plata on the south, extending from the Uruguay river to the Atlantic coast. It has a sea-board of some 120 mi, a shore-line on the Plata of 235 mi. and one of 270 mi along the Uruguay. The southern part of the country is mostly undulating plains, an extension eastward of the Argentine pampas. The coast-line is fringed with tidal lakes and sand dunes; the banks of the two bordering rivers are low, unbroken stretches of level land. The northern section of the republic presents greater variety of relief, with occasional ridges and low ranges, alternating with broad valleys, a true southward extension of southern Brazil. None of the sierras or mountains of Uruguay exceeds 2,000 ft. in elevation. There are no large rivers within Uruguayan territory. The Río Negro, the largest stream, is navigable only in its lower part. No other streams are navigable except for vessels of light draught The Santa Lucía, Queguay and Cebollati are the other principal water courses. The Uruguay river, along the border, is navigable for steamers of 14-ft. draught from its mouth to Paysandú, and above that point for smaller vessels to the falls at Salto, 200 mi. in all.

Geology.—The eastern and southern half of Uruguay is a low, rolling prairie, whose subsoil is of weathered ancient schist and granite, through which protrude low ridges of less weathered rocks. In central and north-central Uruguay a basement of ancient schist is overlain by nearly horizontal Permian beds, which form a low plateau. The northwestern portion is occupied by a southward extension of the Paraná plateau of southern Brazil. This plateau is formed of horizontal beds of Triassic red sandstone of continental origin, in places faulted and capped by sheets of Triassic basalt. The plains of Uruguay are covered with Pleistocene deposits of sand and clay like those found on the pampas of Argentina and with alluvial beds.

Climate.—Uruguay has an excellent climate, the average temperature for the summer months of January and February being 72° F. and that of the coldest month, July, being 50°. Frost is almost unknown. The climate of both summer and winter is marked by great variability from day to day, due to the passing of cyclonic storm centres. Brusque windshifts are common, the hot northerly *sonda* sometimes being followed immediately by the chill *pampero* from the southwest and bringing a sudden drop in temperature. These changes give a middle latitude character to the climate of Uruguay. There are no decided rainy and dry seasons. A rainfall maximum is reached in the autumn (April and May), not in the winter months as is often supposed. Winter rains are most frequent but autumn rains are heaviest. The mean annual precipitation is about 35 in., decreasing with distance from the sea, but everywhere well distributed throughout the year. Many of the summer-time *tormentas* are thunderstorms, convectional and purely local in character. Fogs are frequent from May to October, but seldom last all day on land.

Flora.—Uruguay is primarily a grass-producing country, a true continuation eastward, in this respect also, of the Argentine pampas. There are more trees, however, both native and introduced, than on the pampas, but these are found chiefly in narrow ribbons along the bottom lands of the water-courses. The principal species are the ombú, alder, aloe, poplar, acacia, willow and eucalyptus. The *montes,* by which are understood plantations as well as native

thickets, produce, among other useful wood, the *algarrobo*, the *guayabo*, the *quebracho* and the *urunday*. Indigenous palms grow in the valleys of the Sierra de San José Ignacio, as also to some extent in the departments of Minas, Maldonado and Paysandú The myrtle, rosemary, mimosa and the scarlet-flowered ceibo are common. The valleys within the hills are fragrant with aromatic shrubs The prairies are gay with the scarlet and white verbenas and other brilliant wild flowers

Fauna.—As in most of the inhabited parts of the world, the wild animals have largely disappeared Even the rhea (the American ostrich) is now seldom seen, except in a semidomesticated state Pumas and jaguars are found on the wooded islets and banks of the larger rivers and along the northern frontier The fox, deer, wild cat, the *carpincho*, or water hog, and a few small rodents nearly complete the list of native quadrupeds A little armadillo, the *mulita*, is the living representative of the extinct giants, mylodon and megatherium, whose fossils are found over the pampa There are a few specimens of the vulture, a native crow (lean, tall and ruffed) and many partridges and quails. Parakeets are plentiful in the *montes* and the lagoons swarm with waterfowl The most esteemed is the *pato real*, a large duck. A characteristic sight on the prairies is that of the tiny burrowing owl, sitting on top of every little eminence Large flocks of the lapwing, *teru-teru*, are common, with their habit of warning other game of the approach of danger. Of birds of bright plumage, the humming bird and cardinal—the scarlet, the yellow and the white—are the most attractive, while white herons are frequently seen in swampy lands. The scorpion is rare, but large and venomous spiders are common The principal reptiles are a lizard, a tortoise, the *vibora de la cruz* (a dangerous viper, so called from marks like a cross on its head) and the rattlesnake in Maldonado and the stony lands of Minas Along the upper waters of the Uruguay river the *caimán* (alligator) is not uncommon. Seals are found on small islands off the southeast coast, particularly Lobos island, which so gets its name. (X.)

History.—The first European to visit Uruguay was probably Juan Díaz de Solís, who discovered the Río de la Plata in 1516, although some earlier explorers may have sighted the Atlantic shores of the country. Solís himself was killed by Indians, possibly the Charruas, the very warlike tribe who dominated the region at the time Subsequent Spanish explorers touched the Uruguayan shores of the Plata, but found occupation even more difficult than on the south shore. Long after Buenos Aires, across the estuary, was permanently founded in 1580, Uruguay remained unoccupied. In the 17th century some precarious Jesuit missions existed for a while. Then, in 1680, the Portuguese, who regarded the country as a natural extension of Brazil, founded Colonia. In 1726 the Spanish under Gov. Bruno Mauricio de Zabala of Buenos Aires countered by formally establishing Montevideo. Colonia was taken and given up several times, and until late in the 19th century the region, known as the Banda Oriental del Uruguay, or Eastern Shore of the Uruguay, was a bone of contention between Spain and Portugal and, later, between their respective successors. The result was the creation of an independent-minded people.

When the Wars of Independence broke out in 1810, the great Uruguayan national hero, José Gervasio Artigas, led the independence movement, but insisted upon autonomy for the Banda. Artigas proposed a federal system of government for the Spanish provinces of the Plata basin, and for a time maintained himself supreme over neighbouring provinces which are now part of Argentina; but in 1816, the Portuguese, on pretext of restoring order, invaded the country and after four years conquered it. Independence was reasserted in 1825 and, with Argentine aid, obtained after a war with Brazil. The republic was formally constituted in 1830, but for the next 22 years there was internal factional strife, aided and furthered by Juan Manuel de Rosas, dictator of Buenos Aires His forces, allied with Uruguayan partisans of Gen. Manuel Oribe, besieged Montevideo for nine years (1843–51).

After the declaration of independence, the history of Uruguay became a record of intrigues, financial ruin and political folly and crime. The two great political factors for generations were the Colorados and the Blancos So far as political principles were concerned, there was small difference between them. Men were Colorados or Blancos largely by tradition and not from political conviction. The Colorados held control for many years, and the attempts of the Blancos to oust them caused a series of revolutions, including the revolution of 1910 The military element, moreover, frequently conspired to elect a president amenable to its demands The old Blancos and Colorados were superseded by conservatives or progressives, the latter favouring advanced social legislation.

A new kind of revolution took place with the beginning of the second administration of Pres José Batlle y Ordóñez in 1911. Batlle immediately launched a program of social reform which soon gave Uruguay the reputation of being the most progressive state in South America. Laws providing for the eight-hour day, national insurance, university education for women, state control of monopolies, divorce and the general furthering of education were but some of the measures adopted under Batlle's influence. Immigration was encouraged, and agricultural aid was given through grants of free seed

Uruguay continued to prosper under Batlle's successor, Feliciano Viera (1915–19), who relied upon able advisers from among the young and progressive group who had studied abroad. In 1916 a convention met to discuss a new constitution to replace that of 1830. This came into effect on March 1, 1919, and provided a definite separation of church and state. Decentralization of the national government was brought about, and the executive power was divided between the president and a newly created national administrative council. This constitution continued in effect until 1933, when Pres. Gabriel Terra seized dictatorial power.

Late in President Viera's administration, Uruguay broke off relations with Germany (Oct. 1917) While still professing neutrality, the government formally declared that "no American government forced into war with nations of other continents in the protection of its own rights would be regarded as a belligerent." Shortly afterward several German ships which had been in the harbour of Montevideo since 1914 were seized and, subsequently, leased to the United States for wartime use.

Baltasar Brum, foreign minister under President Viera and a leader in the move for a new constitution, took office as president on March 1, 1919. Uruguay ratified the treaty of Versailles in 1919 and entered the League of Nations.

Uruguay was one of the few Hispanic American republics to escape revolution between 1929 and 1931, but its laudable record was seriously marred in March 1933 when Pres Gabriel Terra, who had been elected in 1931 on a platform of support for the constitutional system of 1919, found himself at odds with the national administrative council and congress, and forcibly dissolved both bodies after a coup d'état. Former President Brum, who resisted, was arrested and was reported to have committed suicide. Terra forced, first, a modification of the constitution to permit his own re-election, and in 1936 submitted a new constitution to the people for approval. This constitution materially strengthened presidential powers. All in all, Terra's rule was a rigid one, but through his dictatorial control, he effected many economies in the nation's finances. In March 1938, Alfredo Baldomir was chosen president for a four-year term in what was regarded by impartial observers as an honestly conducted election

The first year and a half of the Baldomir administration was marked by a slow but steady economic improvement until outbreak of World War II thoroughly disrupted Uruguayan foreign trade. Although Uruguay promptly declared her neutrality, flight of the German battleship "Admiral Graf Spee" to Uruguayan waters (Dec. 1939) brought serious difficulties. During May and June 1940, German "fifth column" activity in the country threatened to bring about revolution and the overthrow of the Baldomir government

Uruguayan declarations of American solidarity were issued promptly after the Japanese attack on Pearl Harbor, and in Jan. 1942 Uruguay severed diplomatic relations with Germany, Italy and Japan In July 1942 Uruguay signed a reciprocal trade agree-

ment with the U.S which, it was hoped, would help to offset its lost European markets and also partially prepare for postwar conditions

Juan José Amézaga, supported by Baldomir and representing the traditionally liberal Colorado party, became president on March 1, 1943 He continued the active collaboration in inter-American defense laid down by his party in 1941–42 The Blanco Nacionalista party, under the leadership of Luis Alberto Herrera, continued to oppose the government. In Feb 1947 the congress declared Tomas Berreta and Luis Batlle Berres, the candidates of the Colorado party, the officially elected president and vice-president. After Berreta died on Aug 2, 1947, Batlle became president Andrés Martínez Trueba, president of the Bank of the Republic and the Colorado party candidate, became president on March 1, 1951 He sponsored a constitutional reform, which was approved by the two leading political parties, to return to the executive council system which had been in effect in 1919–33 When the federal council was installed on March 1, 1952, Martínez Trueba was named chairman

Area and Population.—The area of the republic is 72,172 sq mi, the smallest in South America According to the census of 1908, the population was 1,042,686, official estimates of 1950 gave 2,365,000. The average density of population is therefore about 32.8 per square mile, the greatest of any national area in South America There is a large number of foreign-born inhabitants, most of them Italians and Spaniards, with lesser numbers of Brazilian, Argentine and French birth. Small-scale immigration from northern and eastern Europe continued after 1918 The average annual birth rate was estimated in 1944 at 20.7 per 1,000; the death rate, 8.9 per 1,000. In 1900 the birth rate was 33.43 per 1,000 Montevideo, the capital and most important commercial centre, had an estimated population of 850,000 (1950) More than 75% of the foreign trade of the country passes through Montevideo. Other cities, with their approximate 1950 populations, are Paysandú, at the head of deep-water navigation on the Uruguay river, 50,000; Salto, higher up the Uruguay, 48,000; Mercedes, an agricultural and livestock centre on the lower Río Negro, 33,000; Fray Bentos, important for meat-packing, on the lower Uruguay, 18,000, and Colonia, oldest city in the republic, immediately across the Plata from Buenos Aires, 10,000.

Agriculture.—In 1885 Uruguay imported most of her breadstuffs; however, by mid-20th century not only was wheat grown in sufficient quantities to meet the local demand, but a small surplus usually became annually available for export.

Land for farming purposes is expensive; wages are high, leaving small profit, unless it happens that a man, with his family to assist him, works his own land Wheat, with an officially estimated crop in 1950–51 of 479,202 short tons, is the principle crop. In 1950, 61,500 tons of flour valued at $7,493,000 were exported. Other important crops include oats, potatoes, beans, alfalfa, barley and birdseed. Linseed, oats and potatoes are exported After 1890, cultivation of grapes and the manufacture of wines were extended, especially in the departments of Montevideo, Canelones and Colonia. In 1950, 70,000,000 l of wine were produced Approximately 10% of the land was under cultivation at mid-20th century, and agriculture was subordinate to the pastoral industry in the national economy.

Cattle breeding and sheep farming are the principal industries. At mid-20th century nearly 80% of the land was devoted to grazing, and the stock estimates of 1940 showed 8,700,000 cattle (7,127,912 in 1930) and 23,000,000 sheep (20,558,124 in 1930). There are modern meat-packing establishments in Uruguay where beef and mutton are chilled or frozen for export. Meat exports in 1950 included 68,815 short tons of frozen beef, 23,861 tons of canned beef and 14,482 tons of frozen mutton. Large quantities of liquid extract of beef are also prepared for the European trade. A smaller amount of meat each year is sent to the *saladero* establishments for the preparation of *tasajo*, or jerked beef, for the Brazilian and Cuban markets.

Sheep farming flourishes chiefly in Durazno and Soriano. Uruguayan wool is favourably regarded in foreign markets, because of the clean state in which it is shipped. Sheep are raised largely for their wool Wool exports in the period Oct. 1, 1950, to Sept 30, 1951, were 154,006 bales, of which 118,492 bales went to the U.S., 9,735 bales to Belgium and 5,278 bales to France.

Mining.—Mining is of slight importance in Uruguay Minerals are known to exist in the northern section of the republic, and gold mining is carried on to a small extent. The other minerals found are silver, lead, copper, talc and lignite coal.

Commerce.—Exports are overwhelmingly of raw materials. In 1950, livestock products comprised 89.31% of all exports, with wool aggregating 51.99%, meats, 17%; and hides, 11.53% Agricultural products were 5.88%, of which cereals totalled 5.59% The principal imports are machinery, textiles and clothing, foodstuffs and beverages. Tables I and II show percentages for the leading countries involved

TABLE I —*Exports (1950)*
(In thousands of dollars)

United States	$129,150	50.70%
Great Britain	31,688	12.86%
Belgium	14,657	5.76%
France	14,137	5.57%
Germany	13,081	5.14%
Sweden	8,122	3.19%
Holland	6,314	2.48%
Italy	5,443	2.14%
Brazil	2,450	0.96%
Argentina	1,305	0.51%
Total	$254,281	100%

TABLE II —*Imports (1950)*
(In thousands of dollars)

Great Britain	$45,082	22.45%
United States	30,252	19.94%
Brazil	17,268	8.60%
France	14,416	7.18%
Germany	10,677	5.32%
Belgium	8,596	4.28%
Italy	7,366	3.67%
Sweden	6,730	3.35%
Peru	5,792	2.89%
Venezuela	5,300	2.64%
Paraguay	5,254	2.54%
Total	$200,831	100%

Industrial activity includes manufacturing, power, construction, meat- and fish-packing and metal work

In 1950 production included 60,000 automobile and truck tires; 36,300,000 l. of beer, 3,550,000 lb. of rayon woven goods; and 28,600 short tons of paper. In 1951 there were four *frigoríficos* for treating meat, eight *saladeros* and seven meat-canning plants

Communications.—External communication is largely by water. Waterways are important also for internal communication between Montevideo and ports along the Plata and the Uruguay rivers. In 1948 there were approximately 1,870 mi. of railway In 1950 they carried 9,211,000 passengers and 2,091,930 short tons of freight. Highways in 1948 totalled 36,000 mi., of which 3,051 mi. were paved national roads. On Dec 31, 1949, there were 56,500 automobiles and 20,000 trucks In 1950, 2,072 ships with a net tonnage of 9,241,136 entered the port of Montevideo.

Government.—Under the constitution adopted in 1942, Uruguay's legislative body was comprised of a senate of 30 members and a chamber of deputies of 99 members, in which the parties were given proportional representation. On March 3, 1952, the offices of president and vice-president, established under the constitution of 1942, were abolished The executive was replaced by a nine-man federal council, made up of six representatives from the majority party and three from the minority. The *Colegiado* was established to perform the duties of a regular executive, representing the nation in domestic and foreign affairs and working with the various ministries

Education.—At the beginning of the 20th century, nearly half the population over six years of age was illiterate After that time, however, marked improvement took place Primary education became compulsory and most of the children of school age attend. In 1950 there were 546 urban schools with 157,033 pupils and 1,176 rural schools with 55,476 pupils. The total number of teachers was 6,744 There were also 191 private schools with 36,884 pupils The University of Montevideo had 11,948 students In 1950, 25,457,117 pesos were allocated for primary edu-

cation and 7,047,140 pesos for the university.

Finance.—Actual government expenditures in 1950 were 306,000,000 pesos, revenue, 280,000,000 pesos On June 30, 1951, the internal public debt was 779,504,000 pesos, external, 115,526,000 pesos The cost of living index for Montevideo stood at 207 in July 1951 (1937=100)

The Bank of the Republic (founded in 1896) had a capital of 70,000,000 pesos and a reserve of 26,194,283 pesos on March 31, 1951. In addition to Uruguayan banks, there are branches of a number of foreign banks (of which British, Canadian and North American are the most important) in Montevideo.

The monetary unit, the peso, on Oct 31, 1951, had a value of $0.5263 U S currency, controlled rate, $0.4082 commercial free rate, and $0.4149 uncontrolled rate

Defense.—Composed of volunteers, the army had a strength of 26,000 men in 1950, and the police force numbered about 5,500. During wartime, service in the national guard is compulsory Uruguay also established a small air force and navy. In 1951 the U.S authorized the transfer of two destroyer escorts to the Uruguayan navy.

URUGUAYANA: *see* URUGUAIANA

URUMCHI (URUMTSI, TIHWA), the capital of the Chinese province of Sinkiang, in a valley of the Tienshan, at about 3,000 ft above sea level Estimate of the population in 1936 was 20,000. There is a large Turki element and some Mongols. The place trades in furs and skins It is on the main route from Kansu to Dzungaria and the Ili region

USBEGS. The Usbegs form the ruling clan in Bokhara, Khiva and Kokand, occupying there a very similar position to that of the Osmanli in Turkey They are also found in Samarkand and in some parts of Syr Daria and Ferghana, in which latter place the Kipchak also live, and should probably be classified as Sarts. They are a mixed people, closely allied to the Mongols, and are in a transition from a nomad to a sedentary life.

USHAK or UŞAK, a town of Turkey, in the Kutaiah (Kütahya) vilayet, connected with Smyrna and Konia by rail. Pop (1950) 19,946. It is noted for its heavy pile carpets, *khali*, known as "Turkey carpets." There the Turkish army captured the Greek commander in chief, Gen. Trikoupis, Sept 2, 1922.

USHANT (Fr. *Ouessant*), a rocky, reef-fringed island lying 11½ mi. off the mainland of northwestern France (Brittany). Pop (1946) 2,223. Ushant has a maximum east-west length of 5 mi. and a north-south width of 2 mi. Maximum elevation, 150 ft. Most of the coast is cliffed or high; only on the southeast at Lampoul, the major village, is access easy The population is dominantly engaged in fishing. Garden crops are cultivated and sheep are pastured.

USHAS, in Vedic Hindu mythology goddess of the dawn (from the same root as Lat *Aurora* and Gr. Ἠώς). Celebrated in some 20 hymns of the *Rig-Veda*, Ushas is its most graceful creation. Borne on a car drawn by ruddy kine, the sun is her lover She rises resplendent . . . showing her charms—ever shortening the lives of men she reveals their paths and bestows new life . . . she opens the doors of darkness as the cows their stalls.

USHER or USSHER, **JAMES** (1581–1656), Irish divine and archbishop, was born in the parish of St. Nicholas, Dublin, on Jan 4, 1581 He was sent to a school in Dublin opened by two political agents of James VI of Scotland, who sought to secure a party for James in Ireland in the event of the queen's death.

In 1594 Usher matriculated at the newly founded university of Dublin, whose charter had just been obtained by his uncle, Henry Usher, archbishop of Armagh. He graduated M A. in 1600, became a fellow of Trinity college, and was ordained in 1601. In 1607 he became regius professor of divinity and also chancellor of St Patrick's cathedral, Dublin. In 1613 he published his first printed work, though not his first literary composition—*Gravissimae Quaestionis de Christianarum Ecclesiarum, . . . Historica Explicatio*, wherein he took up the history of the Western Church from the point where John Jewel had left off in his *Apology for the Church of England*, and carried it on from the 6th till past the middle of the 13th century James nominated him archbishop of Armagh in 1625 As archbishop he discountenanced (1629) Bishop William Bedell's proposal to revive the Irish language in the service; he shared in drafting (1634) the code of canons of the Irish Church, and defeated the attempt to make the Irish Church conform exactly to the doctrinal standards of the English In 1640 he paid another visit to England on one of his usual scholarly errands, meaning to return when it was accomplished. But the Great Rebellion of 1641 prevented his return Usher pleaded in vain with Charles I not to abandon Strafford. By way of compensation for the loss of his Irish property he received the temporalities of the vacant see of Carlisle In 1643 he declined a seat in the Assembly of Divines at Westminster He quitted Oxford in 1645 and went into Wales, where he remained till 1646, when he returned to London, and was in 1647 elected preacher to the Society of Lincoln's Inn, an office which he continued to hold until near his death In 1648 he conferred with Charles I in the Isle of Wight, on the abortive negotiations with parliament on the question of episcopacy. In 1650–54 he published the work which was long accounted his most important production, the *Annales Veteris et Novi Testamenti*, in which he propounded a now disproved scheme of biblical chronology, whose dates were inserted by some unknown authority in the margin of reference editions of the Authorized Version In 1655 Usher published his last work, *De Graeca LXX Interpretum Versione Syntagma*. He died on March 20, 1656, in Lady Peterborough's house at Reigate, and was buried in Westminster abbey

Usher's works are very numerous, and were first collected by C. R. Elrington and J. H Todd (Dublin, 1847–64) in 17 vol. See *Life* by Carr (1895); W. B. Wright, *The Usher Memoirs* (1889).

USK, THOMAS (d. 1388), the author of *The Testament of Love*, a prose work formerly attributed to Geoffrey Chaucer, was born in London, Eng In 1897 Henry Bradley interpreted the acrostic comprised of the initial letters of its chapters—"Margarete of virtw, have merci on thus Usk"—as a statement of authorship. Thomas Usk was clerk of the closet to John of Northampton when he was mayor of London, 1381–83. In 1384 Usk was put in prison, but he was released on promising to bring charges against Northampton, who had been arrested for treason. Usk freely produced evidence which sent Northampton to prison. Usk fell with the king in the successful rebellion led by the duke of Gloucester, the king's uncle, in 1387. Tried for treason in 1388, Usk was condemned to death. At his execution, March 4, 1388, he was first hanged and then beheaded by 30 blows with a sword

The *Testament of Love*, which includes passages similar to the translations of Boethius by Chaucer, is a work of almost 60,000 words. It portrays the author in prison as he has interviews with an apparition in the form of a beautiful lady called Love. Excessively tedious, its obscurity and dullness was demonstrated by the fact that successive editors did not discover that the leaves of the original manuscript had been shuffled and the body of the treatise misarranged. No manuscript of the work was preserved; it was first printed by William Thynne in his edition of *Chaucer* (1532). In 1897 Walter William Skeat, with cancelled sheets to cover the unlucky mistake referred to above, issued a revised and annotated text in his *Chaucerian and other Pieces.*

USK, a small market town and urban district on the Usk river, Monmouthshire, England. Pop. (1938) 1,228 Area, 1 02 sq.mi. It was a Roman fort, *Burrium*, and there are ruins of a castle built

by the Clares in defense of the Welsh marches. The castle was taken by Simon de Montfort in 1265 and suffered under Owen Glendower. The church of St. Mary perpetuates a Benedictine nunnery founded by Richard de Clare in 1236. There is 12th-century work. Usk is well known to anglers. The ancient corporation was abolished under the corporations act of 1883.

USK, a river of Wales and England, 70 mi. long, flowing to the Bristol channel. The source is the north flank of Carmarthen Van, a summit of the Brecon Beacons; the course passes Brecon, Crickhowell, Abergavenny, Usk and Caerleon. The river is noted for its salmon and trout fishing.

USKOKS, a Serbo-Croat name meaning "refugee," applied to certain Christians who, after the Turkish conquest of Bosnia in 1463, fled, first to Glissa, in Dalmatia, then to Zengg, in the Croat military frontier. They turned to piracy, and became the terror of Adriatic commerce, which was largely Venetian. They received covert support from Austria, and an unsuccessful attempt by Turkey in 1592 to capture Zengg led to war between Turkey and Austria. In 1602 Austria allowed Venice to send a force against Zengg; it was defeated; and the piracy went on until in 1615 it led to war between Austria and Venice. The treaty of Madrid (1617) provided that they be disbanded and their ships destroyed; they were transported inland to the mountains to which they gave their name.

USTARANA, a Pathan tribe living to the extreme south of Dera Ismail Khan in the North-West Frontier of India.

USTER (1,532 ft.), a town in the canton of Zürich, Switzerland, near the Greifen See and on the railway Zürich-Rapperswil. It is an industrial centre with 10,588 inhabitants in 1941, speaking mostly German and chiefly Protestant.

ÚSTÍ NAD LABEM or AUSSIG A. D. ELBE, a town in N.N.W. Bohemia, in a highland district at the confluence of the Bela and the Elbe, is an important Elbe port. Pop. (1930), 43,802, mostly German. The town was ceded to Germany in 1938 by the pact of Munich

USTYUG VELIKIY, a town in the Archangel region of the Russian S.F.S.R., lat. 60° 47′ N., long. 46° 22′ E. Population 19,092. The town is the focus of post roads to Vologda and Gorky. It has distilleries, breweries, timber mills, leather factories and workshops for the production of agricultural machinery. It has two annual fairs. Special crafts include silver engraving and the making of boxes with secret locks.

USURY. The practice of lending at interest which exceeds a lawful or reasonable rate. For an account of professional moneylenders, legal rates of interest and legal control over usurious transactions, *see* MONEY-LENDING.

A long legal development has accompanied the allowance of interest against defaulting creditors. By Roman law the defaulting party to a contract was compelled, beyond fulfilment of the agreement, to pay compensation for the difference (*id quod interest*) to the creditor's position caused by his default. This difference could be based on actual loss accrued, and also on the profit that might have been made had performance been carried out. Mediaeval lawyers used the phrase *damna et interesse* for such compensation, and for damages and indemnity generally. Thus *interesse* became applied to the charge for the use of money, disguised as an indemnity for failure to perform a contract. At English common law an agreement to pay interest was only implied when supported, as in the case of negotiable instruments, by mercantile usage, or by the constant practice of a trade or business, or by the course of dealing between the parties. Otherwise an express agreement was required. By the Civil Procedure Act of 1833, provision was made for the allowance of interest at a rate not exceeding the current rate of interest upon debts evidenced by a written instrument from the time when their payment became due and in debts not so evidenced from the time a written demand for their payment had been made. In the United States the law regarding the allowance of interest has been more liberal. When there is default in the payment of a money debt, interest at the legal rate is allowable as damages for the delay in payment. Many States upon a similar theory allow interest upon unliquidated contractual demands where the default consists in something other than a failure to pay money. As in England, no interest is allowable upon claims for damages consequent upon a tort, but in America interest upon damages for torts to property is generally allowed In both countries compound interest is only claimable by express agreement or by established mercantile practice

In the United States a most significant development in the field of usury is the attempt to control the lending of small sums of money at usurious rates. The early statutes were ineffective to prevent usurious interest being demanded of necessitous borrowers, fixing rates of interest so prohibitively low as to drive the business outside the law. To remedy this situation a Uniform Small Loan Law, since adopted in many States, required licenses of lenders making loans under $300, supervised the conditions under which such loans were made, and permitted an interest rate not exceeding 3½% a month on unpaid balances. This legalizing of the small loan business at adequately remunerative rates has been highly effective, driving the illegal and extortionate lender from the field and opening it to the lawful investment lender from the field and opening it to the lawful investment of capital. *See* Ham, *Small Loan Legislation* (1922) (J. M LA.)

In the United States, where a penalty for usury is fixed both by State and Federal statutes, it is well settled that the penalty fixed by Federal legislation is superior to and exclusive of any State penalty.

UTAH, long called "Deseret," which in the *Book of Mormon* language means "a honey bee," is one of the Rocky mountain states in the western part of the United States. It is situated between approximately 37° and 42° N. and 109° 3′ and 114° 3′ W. Its area is 84,916 sq mi , of which 2,570 sq mi. are water surface. The area is equal to that of England and Scotland combined Utah was the main habitat of the Ute tribe of Indians.

Physical Features.—A line drawn with a slight westward concavity from the middle of the northern boundary to the southwestern corner would divide Utah into its two main physiographic regions, the Great Basin to the west and the plateau region to the east. For a long distance this line would follow the high crest of the Wasatch mountains, a magnificent range running north and south, forming the great backbone of the state, and dividing the drainage of the Colorado river system from that of the Great Basin. Centuries ago the Great Basin region was covered by a vast expanse of water, about 19,000 sq.mi. in area, known to geologists as Lake Bonneville. Shoreline at 17 distinct levels can still be traced on the mountain side. Great Salt lake is a shrunken remnant of this inland sea, and the rest of the basin is its one-time bed. The land of the basin floor, parched and barren in its uncultivated state, unless alkaline, is very fertile, and produces abundantly when irrigated. Along the eastern fringe of the basin, where the land can be watered by the streams flowing down from the Wasatch range, are to be found the most populous districts of Utah. The monotony of the level basin floor is broken here and there by steep isolated north and south mountain ranges of monoclinal structure which rise abruptly several thousand feet above the plain. There is no drainage outlet, so the streams merely flow into the low places where, during the dry season, the water evaporates, leaving barren "mud flats" on the basin floor. In the larger depressions the water does not entirely evaporate but remains, forming saline lakes whose areas increase and decrease with the season The largest of these is Great Salt lake, having an area at its greatest extent of 2,000 sq.mi. One-third of this area is lost annually by evaporation. Its waters at mid-20th century contained an average salt density of approximately 25%, or about five times that of the ocean. The lake is fed by Bear river from the north, Weber river from the northeast and Jordan river from the southeast. The Jordan carries the overflow from Utah lake, a fresh water body 127 sq.mi. in area. Southwest of Great Salt lake is a broad flat stretch, more and and barren than the rest of the basin, known as the Great Salt Lake desert. It is low, and in the spring covered partly by water. The Great Basin as a whole rises gradually and imperceptibly from an elevation of 4,300 ft. at the shores of Great Salt lake to an altitude of about 6,000 ft in the south of the state.

East of the Wasatch range is the so-called plateau region, much higher on the average than the Great Basin but deeply cut by valleys and canyons, which carry its drainage to the Colorado river. On the north this area is bounded by the Uinta mountains, the highest range in Utah and the only important range in the United States to run directly east and west. It extends at right angles to the Wasatch range and almost meets it on the west. King's peak (13,498) is the highest in the state, Mt Emmons (13,428), Gilbert peak (13,422), Mt Lovenia (13,250) and Tokewanna peak are the others rising above the 13,000-ft. mark. Between the peaks local glaciation has carved deep amphitheatrelike valleys, many of them containing alpine lakes, wild and difficult of access. South of the Uintas the plateau summits rise to 9,000, 10,000 and 11,000 ft. They are generally forested, but are too high and difficult of access to be inhabited The people of this region live in the valleys along the streams between the plateaus. Southeast from the Uinta mountains fossilized remains of dinosaurs and many other prehistoric animals have been found. Dinosaur National monument has been created in this area 6 mi. from Jensen on U.S. highway 40. Dinosaur remains have been found in other areas including Escalante valley and the San Rafael swell South toward the Colorado river the plateaus drop rapidly in a series of brightly coloured sandstone cliffs resembling giant terraced steps, and are named from the colour of the outcropping sandstone The Pink cliffs are the highest and most conspicuous; then come the White cliffs, Vermilion cliffs and Grey cliffs In this southern portion also are several interesting mountain groups which do not properly belong to the plateau system. They have been formed by the intrusion of molten igneous rock between the layers of sediments, causing the overlying layers to arch up into dome mountains. Such groups are the Henry mountains, west of the Colorado, and the La Sal and the Abajo mountains, east of the Colorado Southeast of the Colorado, and especially in the region drained by the San Juan river, there are few areas capable of cultivation; the soil is sandy and the population scanty Much of the area is relatively inaccessible even by pack horse, for trails and watering places are few. Yet there some of the most picturesque scenery of Utah is to be found. The richly coloured sandstone has been moulded by erosion into such figures as the Navajo Twins, Organ rock, Needle rock, Train cliff and Ostrich rock In Natural Bridges National Monument slender spires and mighty bluffs lift steep red stone sides perpendicularly to great heights The region abounds in natural bridges, including the Rainbow bridge, 309 ft. high and 274 ft between its abutments. Dainty Kachina, with a width of 186 ft. and height of 205 ft., and the Sipapu, 222 ft. high and 261 ft long, are wedged in the White canyon Innumerable prehistoric ruins and cliff dwellings are found in this region also.

The region has been only partly explored archaeologically, and new ruins are constantly being reported. Some caves have been found to contain remains of the Basket Makers, predecessors of the cliff dwellers. Many caves are covered with Indian pictographs and large paintings of animals. The whole region of southeastern Utah, a vast and weird land, was one of the last parts of the United States to be explored. It was not until 1904 that the outside world heard of its natural bridges, largest in the world.

Besides the great canyons of the Colorado, the Green and Grand rivers, there are many of similar grandeur in the tributary streams The San Juan canyon is sometimes called the "Little Grand Canyon of the Colorado." On the Rio Virgin in southwestern Utah is Little Zion canyon, set aside as Zion National park. It was named by the Mormons who discovered and settled it. In Bryce canyon there are acres of fantastic tower and turret formations formed by erosion only, the softer red rocks being capped by a harder stratum which resists weathering

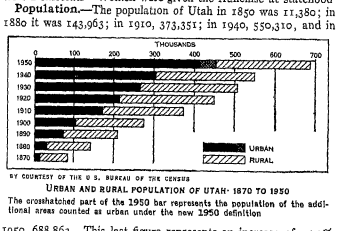
In Utah climatic conditions vary by altitude as well as by latitude. Moderate summer temperatures are found in the mountains and on the plateaus. Precipitation also varies with the altitude, from 42 in. at Silver lake in Brighton to 5 or 10 in in the lowlands, and to 4.9 in. at Salduro in the deserts. The higher plateaus and mountain ranges bear forests of fir, spruce and pine, and the lower slopes are dotted with pinon, juniper and scrub cedar. Willows and cottonwoods grow along the streams Sagebrush is characteristic of the desert areas, and on the hillsides bunch grass affords valuable pasturage Bird life is prolific Besides the usual varieties found in the Rocky mountains, white pelicans established a rookery on Hat Island, so named from being shaped like a cowboy's hat, now known as Bird Island, where there are vast numbers of pelicans, blue herons and sea gulls. Many geese (snow, Canada, black brant and others) thrive about the lake. Bird sanctuaries have been provided by law, chief among which is the Bear River Bird refuge at the mouth of Bear river where it enters Great Salt lake.

History.—Utah was acquired by the United States from Mexico in 1848 by the Treaty of Guadalupe Hidalgo, which terminated the Mexican War. Before Mexico had become an independent nation, however, Utah was a part of Spanish possessions and the Spaniards were its first explorers. The first extensive exploration occurred in 1776, when Father Silvestre Vélez de Escalante and Father Francisco Dominguez set out to find an overland route from Santa Fe to Monterey, on the California coast. Crossing southwestern Colorado, they entered Utah in the east about where the Grand river enters the state, continued west across the Green river, followed an Indian trail over the Wasatch range, and descended the Spanish Fork to Utah lake, where they camped and preached to a large gathering of Indians From them the fathers heard of a great salt lake to the north, but they did not visit it. Instead they headed southwest, crossing the divide to the Sevier river and then across the Sevier desert. There their guide deserted them, so they decided to return to Santa Fe The fathers did not fully accomplish their purpose, but the first part of their route later became part of the Old Spanish trail from Santa Fe to Monterey. Three separate parties of U.S trappers under William Wolfskill and Ewing Young journeyed over the entire route in 1830 It was also the road taken by John Frémont on his return eastward in 1843–44.

The first Americans to penetrate Utah or the Great Basin region, apparently, were the four men, Miller, Hoback, Robinson and Rezner, detached in 1811–12 from the overland expedition of John Jacob Astor to trap in eastern Idaho. Their vague account seems to indicate that they crossed northeastern Utah. There has been much discussion as to who discovered Great Salt lake On a map of North America engraved for Gutherie's *New System of Geography* (1811) a considerable lake with no outlet is represented in the same position approximately as Great Salt lake, and it bears this legend "Lake, etc., laid down according to Lawrence, who is said to have travelled through to California in 1790–91." As nothing further is known of Lawrence, credit is usually given to James Bridger, who came into the country with a trapping expedition sent out in 1824 by William Ashley of St. Louis. The expedition was divided into detachments, Bridger accompanying that which wintered on Bear river, while Étienne Provost led another which may have wintered on Great Salt lake. If so, Provost was the discoverer of the lake, for Bridger did not make his discovery until the spring of 1825, when, to settle a wager as to the outlet of Bear river, he went down its course to the lake Finding it salt he believed it was an arm of the ocean. In 1826, the next year, Jedediah S. Smith started from Great Salt lake to explore the unknown southwest to the Pacific. On his return he struggled 20 days across the deserts of Nevada and Utah to reach Great Salt lake, which he did without loss of a man. It was the first expedition to cross the western country by the central route or to penetrate any distance into the basin west of Great Salt lake, so opening up a vast territory.

On July 23, 1847, the first Mormon company entered Salt Lake valley. Next day their leader, Brigham Young, proclaimed: "This is the place." From Feb. 1846, when they were forced to leave Nauvoo, Ill., they had been on the move. About 15,000 Mormons crossed Iowa that summer, and wintered along the Missouri in camps they built. In April, Brigham Young's advance party of 143 men, 3 women and 2 children left Iowa with 73 wagons loaded with seeds and implements. In July Parley P. Pratt's party of 1,550 started with 580 wagons. This party, typical of later ones, was divided into companies of 100 wagons, and these again

into companies of 10, each with its captain Horses, cattle, sheep, hogs and chickens were taken along About 2,000 Mormons were in Salt Lake valley at the end of autumn in 1847 In 1848 other parties were on their way, and about 1,000 wagons arrived that year But this did not end the expeditions Missionaries were working throughout the east and in Europe, especially in England and the Scandinavian countries, preaching of the new Zion Party after party crossed the plains by ox teams in the years following, until the Union Pacific railway was built in 1869 Many of the immigrants came from far lands. A fund was provided by the church to aid the poor, and the money was returned as soon as the immigrant could afford to pay In 1856 there was such an increased number of poor refugees from Europe that a cheaper way to transport them to Utah was needed So handcarts were provided them at Iowa City, the terminus of the railroad, and three expeditions set off during the summer The first reached Utah safely, but the last two were caught by winter storms on the plains, and before they could be rescued 66 of the first party and nearly 250 of the second died from lack of food and the cold



The winter of 1848–49 severely taxed the resources of the pioneer community at Salt Lake, but after the emigration of gold-seekers to California began in 1849 matters brightened A large percentage of the teams came by way of Salt Lake City and found the settlement a welcome stop on their journey. The Mormons traded with them, receiving high prices for fresh horses and food supplies In Feb 1849, after the southwest was transferred to the United States, a convention was called to organize a state under the name of Deseret The petition for statehood was sent in at once and a provisional state government set up to function meanwhile In the first election Brigham Young, already the president of the church, was elected governor. Instead of gaining statehood at this time, Deseret was only made a territory and its name was changed to Utah. Young's election was confirmed by appointment from the president. In contrast with other western states, order and harmony prevailed in Utah before the government was established because the church superintended matters and acted as a government. Its officials distributed provisions, apportioned lots and farm plots, and ordered what work was to be done and the methods to be followed. Even after the territorial government was under way, the church continued to direct affairs and so often came into conflict with the appointive officers sent out by the federal government, and with non-Mormons. (*See* MORMONS.)

The very same afternoon that the advance body of Mormons reached the valley of the Great Salt lake, three plows were put into the soil, potatoes were planted and the waters of City creek turned over the plot. Thus began the agricultural life upon which their communities were founded, and thus also began the irrigation that was to make agriculture possible. The Mormons were the first to practise irrigation on a large scale in the United States. The farm area grew quickly along the western slopes of the Wasatch range, but the church did not rely on that only. Explorers were sent in all directions to select the most fertile valleys with plenty of convenient water available. Colonists were then selected, 30 or 40 families from those that were constantly coming, to go and settle each valley. In 1848 the Ogden valley was settled, in 1849 the Sanpete valley and Utah valley, and in 1851 the valley of the Little Salt lake. In time there were few valleys in Utah that Mormon colonies had not settled, spreading out like bee swarms from the mother hive at Salt Lake City. They settled by church congregations, as in early New England, and all the temporal, social and spiritual activities of the people were under direction of their ecclesiastical leaders Most of the manufactured articles needed were made in the home, though small grist and saw mills and tanneries were quickly set up. In 1850 the U.S. census gave the value of manufactures in Utah as $291,220. Merchants were establishing stores and bringing their stock over the plains from the east by long freight trains, one of them in 1853 numbering more than 400 wagons. Coal was early sought, and the mines developed. In 1849 iron was discovered, plans for an iron foundry laid, and the call sent to Europe for "blowers, moulders and all kinds of furnace operators." In 1852 the first pig iron was made. Erastus Snow went to England to study the great iron factories of that country and in 1853 became president of the newly incorporated Deseret Iron company The mining of precious metals, however, was discouraged by Young, partly because he felt prosperous farms made better homes than the feverish, impermanent mining camps; and partly because he knew gold discoveries would draw hordes of "Gentiles," out of harmony with his ideals and plans, to his colony. In 1863 when Col Patrick E Conner brought his company into Utah, he allowed his men, many of whom were old California miners, to prospect, and he also actively aided them He himself staked the first claim in the state. Thus even during Young's lifetime many mines were opened The early ore was sent to Wales for smelting, but in 1870 the Woodhull brothers of the Little Cottonwood mine completed the first smelter. In 1871 the Walker brothers built the Pioneer Crushing and Amalgamating mill with 15 stamps to work the silver ore of the Ophir mine, which they had located the previous year The coming of the Union Pacific railway in 1869 greatly stimulated mining It also brought an influx of non-Mormons who were to increase steadily as the years went by The Utah Central and the Utah Southern railways built extension lines to the Bingham, Little Cottonwood and American Fork mining districts. Later the Utah Eastern passed up Parley's canyon and helped in the development of the Park City mines.

Six separate efforts, in 1849, 1856, 1862, 1872, 1882 and 1887, to gain statehood were made by Utah Each time a constitutional convention met, a constitution was drawn up and a petition sent to the federal government They were refused statehood because of their polygamous practices The U S government had enacted legislation in 1862, 1882 and 1887 forbidding polygamy Resistance was made by the Mormons which resulted in fines, imprisonment and, in the case of Pres John Taylor, exile. Church property amounting to $100,000 was temporarily confiscated. Finally in 1890 the church yielded and refused henceforth to sanction plural marriage The final movement for statehood came from the U.S congress in 1893, when it passed the enabling act, one of the provisions of which was that the constitution of the new state should forever prohibit polygamous marriages. The constitution was framed at a convention in 1895, submitted to the voters at the general election in November and approved The proclamation of admission was signed by the president on Jan. 4, 1896.

Politically Utah remained essentially independent. Five Republicans and four Democrats had served as governor by 1950 In national elections the state by 1950 had voted Republican seven times and Democratic seven times. In 1951 the two senators and the governor were Republicans. The congressman and congresswoman, Utah's first woman elected to congress, Judge Reva Beck Bosone, and all elected state officials except the governor were Democrats Women were given the franchise at statehood

Population.—The population of Utah in 1850 was 11,380; in 1880 it was 143,963; in 1910, 373,351; in 1940, 550,310, and in

BY COURTESY OF THE U. S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF UTAH: 1870 TO 1950

The crosshatched part of the 1950 bar represents the population of the additional areas counted as urban under the new 1950 definition

1950, 688,862. This last figure represents an increase of 25.2% over the population in 1940. The population per square mile in 1950 was 8.4, as compared with 6.7 in 1940 and with 50.7 for the U.S. in 1950

Of the 1950 population, 472,518 or 59.9% lived in incorporated

places of 2,500 or more, as compared with 55.5% in 1940, when these places constituted the urban area. The entire urban population, under a new definition set up for 1950, which included also the thickly settled suburban area, or "urban fringe," adjacent to Salt Lake City, and three unincorporated places of 2,500 or more outside this fringe, amounted to 449,855, or 65.3% of the state total.

Area	Population			Per cent of increase	
	1950	1940	1930	1940–50	1930–40
The state	688,862	550,310	507,847	25.2	8.4
Urban	449,855*	305,401	266,204	47.3	14.7
Rural	239,007*	244,817	241,583	−2.4	1.3
Per cent urban	65.3*	55.5	52.4	.	.
Principal cities					
Salt Lake City	182,121	149,934	140,267	21.5	6.9
Ogden	57,112	43,688	40,272	30.7	8.5

*Final figures for 1950 based on new definition *See* comment in text

The number of households in 1950 was 188,085, as compared with 139,487 in 1940. The average population per household had declined from 3.9 to 3.6 in 1950.

Government.—The constitution of Utah was formed by a convention at Salt Lake City, March 4–8, 1895, submitted to the people on Nov. 5 and ratified by a vote of 31,305 to 7,687. It came into effect Jan 4, 1896, the day Utah was admitted to the union. It provides that no law can be passed restricting the freedom of the press or the establishment of religious sects. There is no imprisonment for debts unless the debtor absconds Males and females enjoy equal privileges in civil, political and religious rights One provision, which guarantees religious freedom, forbids sectarian control of public schools, prohibits polygamy and defines the relation of the state to the public lands of the United States, is irrevocable unless with the consent of the U.S government. All citizens of the United States who have lived in Utah a year, in the county four months and in the precinct 60 days have the right of suffrage Only those who have paid a property tax the year before may vote in elections levying a special tax creating indebtedness or increasing the state rate of taxation.

The powers of government are divided into three distinct departments, the legislative, executive and judicial. The legislative power is vested in (1) a senate and a house of representatives, and (2) the legal voters, who are given the power of initiating desirable legislation and of referendum on all laws not passed by a two-thirds vote of both houses No person is eligible for office in the legislature who is not a citizen of the United States, 25 years of age or more, a qualified voter in the district from which he is chosen, and a resident of Utah for three years and of his district for one year. Regular sessions of the legislature are held in odd-numbered years, opening on the second Monday in January. They cannot last more than 60 days except to try cases of impeachment. Representatives are elected for two years; senators for a four-year term, one-half the number retiring every two years. The number of senators must not exceed 30 and the representative body must be at least twice as large as the senate. In 1950 there were 23 senators and 60 representatives.

The executive officials are the governor, secretary of state, state auditor, state treasurer, attorney general and superintendent of public instruction. The auditor and treasurer are ineligible to election as their own successors. The governor and secretary of state must be at least 30 years of age, the attorney general at least 25 and in good standing at the bar. The governor has the right of veto unless overruled by the bill being repassed with a two-thirds majority in both houses. The governor, justice of the supreme court and attorney general compose the board of pardons. The board of examiners consists of the governor, secretary of state and the attorney general

The judicial power is vested in the senate sitting as a court of impeachment, a state supreme court, district courts, city courts, justices of the peace and other courts inferior to the supreme court as established by law.

Finance.—Major sources of the $79,926,327.38 in revenue receipts to Utah in the fiscal year ended June 30, 1950, were (1) emergency revenue tax, known more familiarly as the 2% sales tax, supplying $14,013,055.21 or 17.53% of total receipts; (2) federal grants, $12,031,184.42 or 15.05%; (3) motor use and fuel taxes and motor-vehicle registration and control fees, $10,118,495.10 or 12.66%; (4) property tax, yielding $6,729,599.05 or 8.42%; and (5) individual income tax, $4,105,477.44 comprising 5.1% of total receipts

Two other sources of revenue should be mentioned· (1) the state-managed liquor-control agencies, which supplied $12,540,917.79 or 15.69% of total state revenue; and (2) educational licences and fees, which amounted to $3,763,356.95 or 4.7% of total revenue. It should be noted, however, that these two sources of revenue did not represent net receipts Total liquor-control expenditures (including $1,000,000 allocated to cities, towns and counties) amounted to $9,786,537.98, leaving a net profit to the state of $2,754,379.81. The sum of $6,411,593.62, an amount $2,648,236.67 greater than the total collected by the state in the form of educational fees, was disbursed for universities and colleges A total of $14,827,478.97 was allocated to the school districts in accordance with a school law, passed by the 1947 legislature, which provided for a minimum expenditure of $3,300 per classroom unit throughout the state; this procedure being adopted to further equalization of educational opportunity. The property-tax levy for state school purposes in the calendar year 1948 was 8.9 mills. The mean local rate was 35.13 mills. Total assessed valuation of the state in 1949 was $823,749,300. Federal appropriations received by the state during the 1950 fiscal year were broken down as follows: (1) roads $3,893,688.74, (2) public health and welfare $6,105,398.61, (3) education $1,399,795.99 and (4) miscellaneous grants $632,301.08

Utah is one of the principal mineral-producing states of the country, and its mine occupation tax yielded $865,579.01 or 1.08% of total receipts. Proceeds from cigarette, corporation, franchise, beer and other taxes; fines and forfeitures and miscellaneous revenue receipts, including contributions from local governments ($134,859.81 or .17% of total receipts); teachers' contributions to the retirement fund, and all other items aggregated $15,758,651.51, which brought total receipts of the state during the fiscal year to $79,926,327.38.

The total disbursements were $76,366,125.10. Largest item was the total of $25,183,201.95 or 32.97% spent for schools and educational agencies. This included the amount allocated to school districts and disbursements to universities and colleges mentioned above. Next largest item was the $15,157,289 or 19.84% spent for public health and welfare. A total of $13,652,647.76 or 17.87% was spent on roads and aeronautics, aeronautics claiming $193,889.99 or .25%. Building commission projects disbursements totalled $2,572,233.76 or 3.36%, and $945,711.32 or 1.23% went for fish and game control administration. Liquor-control purchases, administration and allocations to cities, towns and counties comprised $9,786,537.98 or 12.81% of the state's expenditures. The remainder of the $9,068,503.33 (11.87% of all disbursements) went to maintain the courts and the penal, military and police needs of the state, to pay the salaries and expenses of the state officials and the legislature; and for other miscellaneous expenses incidental to government.

The outstanding bonded indebtedness in 1936 was $10,573,000, but in 1943 Utah became one of the few states out of debt. The 1943 legislature set aside $2,014,146.72 to retire the remaining bonded indebtedness of the state. Since the dates of maturity of the state bond issues were extended over a period of time from March 1939 to March 1955, it was not possible to redeem all outstanding issues immediately, but money was provided to redeem all bonds at the maturity dates In Nov. 1950 there remained $770,000 in bonds outstanding. To cover this amount the state had invested $1,150,000 in bonds. There was also $26,751.33 in cash on hand.

In 1950 there were 44 state and 11 national banks with total assets of $608,613,517.85. This amount compared with total assets of $198,862,061.75 in 1940. Total time deposits in 1950

amounted to $177,644,227.70, as contrasted with $64,348,859 in 1940. Demand deposits in 1950 totalled $387,180,462.43.

Education.—School attendance for at least 30 weeks annually is compulsory for all children from 8 to 18 years of age, unless they are lawfully excused. As a result, 150,586 pupils, or 91% of a school census population of 151,465, were enrolled in 1948–49; 88,100 of these were elementary pupils and 62,486 high school There were 2,521 elementary school teachers, 990 junior high school teachers and 1,150 high school teachers. Figures for 1947–48 showed that 5.5% of Utah's schools were one-room schools. Only one other state, New Jersey, with 4 9%, had a lower percentage There were 305 elementary schools, 28 junior high schools, 29 senior high schools, 58 combination elementary through senior high schools and 34 combination junior and senior high schools in the public system in 1948–49. In addition to Brigham Young university there were four private professional schools, two private colleges and six other private schools teaching from the elementary to the high-school level. There were four junior colleges and two area vocational schools, one at Salt Lake City and one at Provo, supported by the state. The expenditure for education in Utah increased from $92.46 per capita of school population in 1939–40 to $254 13 in 1948–49.

The income for elementary and secondary education in 1948–49 was $38,527,128 79 of which $14,359,802.64 was provided from the state funds and $23,061,693.41 from local sources. The expenditure for 1948–49 totalled $38,491,957.61 (including capital outlay and interest). Expenses for instruction were $17,268,584.21 and for operation and maintenance of school plant $3,344,931. The average salary for teachers, supervisors and principals was $3,054. Private and parochial schools, in addition to Mormon seminaries, in 1950 employed 215 part-time and full-time teachers for an approximate total enrolment of 4,966 students. This figure compared to an enrolment of 1,465 in 1939–40. The Mormon Church in 1950 maintained 77 religious seminaries near junior and senior high schools, with an enrolment of 19,547 as compared with an enrolment of 15,361 in 1939–40.

The University of Utah, at Salt Lake City, was organized in 1850 as the University of Deseret and placed under the control of a chancellor and board of 12 regents appointed by the governor. It closed in 1851 for lack of funds and did not reopen until 1867, though during all this period the board was regularly appointed and functioned in supervising the public schools. In 1869 the university was reorganized to include classical and normal schools, and in 1892 was given its present name. The registration in 1949–50 was 9,703 for the regular session with an additional 7,172 registered for summer school, evening residence classes and extension work. The Utah State Agricultural college at Logan had an enrolment in 1949–50 of 4,992 with an additional 1,281 enrolled in summer school and 1,195 in extension classes. The Church of Jesus Christ of Latter Day Saints (Mormon) maintains the Brigham Young university at Provo which had a regular enrolment in 1949–50 of 5,904 plus 1,525 enrolled in summer school and 1,380 students taking extefision classes. The Mormon Church at this time also maintained seven religious institutes with a total enrolment of 3,819 near the Uiversity of Utah and colleges and junior colleges. Other private schools are St. Joseph school at Ogden, College of St. Mary-of-the-Wasatch, Rowland Hall, Judge Memorial and Westminster college at Salt Lake City; Notre Dame de Lourdes at Price; and Wasatch academy at Mt. Pleasant. The four main private professional schools in the state in 1950 were the McCune School of Music and Art, the Latter Day Saint Business college, Henagers Business school and the Ogden Business college.

Charitable and Penal Institutions.—Final stages of the movement of the state prison from its old Sugarhouse location in Salt Lake City to the new, modern plant at the "point of the mountain" in Salt Lake county were completed in 1950. The number of prisoners for November of that year was listed as 561, including 3 women prisoners incarcerated at Canyon City, Colo. Prison labour cannot be let out on contract, but "honour prisoners" are allowed to work on roads and irrigation projects, on additions and repairs to prison buildings and on the prison farm surrounding the prison itself. The state industrial school at Ogden, established for delinquent boys and girls, endeavours to help them by teaching for delinquent boys and girls, endeavours to help them by teaching manual training, home economics, printing and mechanical repair work. A school for the deaf and blind, also at Ogden, teaches caning of chairs, broommaking and printing and linotyping. The Utah Trainng school at American Fork was built for mentally incapacitated children Utah permits sterilization of the mentally deficient; this is done before the children are released from the training school. The state mental hospital at Provo cares for the insane.

The state also maintains the Utah state tuberculosis sanatorium at Ogden.

Agriculture and Livestock.—In 1945 Utah farm lands made up 19 6% of the total land area of the state. Agriculture is, where possible, dependent almost entirely upon irrigation. Soil that can be watered is generally very rich In early days under the Mormon system, farm plots were only 5, 10 or 20 ac. Gradually the average size of farms grew until in 1900 it was 212 4 ac ; it dropped to 203 ac. in 1935, then increased to 392 ac in 1945 The total acreage in farms in 1945 was 10,309,107, compared with a figure of 6,239,318 in 1935. Total cropland in 1945 was 1,663,702 ac., approximately 3% of the state's total area. Roughly 1% of Utah's cropland is devoted to dry farming and 2% is irrigated. Total cash receipts from farm marketings in 1949 were $150,569,000 Receipts from livestock and livestock products, $103,114,000, amounted to more than two-thirds of the total. Market receipts from crops amounted to $47,455,000. Between 1935 and 1945 the acreage of farm land increased 4,069,789, but farm population fell from 138,242 to 99,989. The value of farm lands and buildings increased from $158,303,329 in 1935 to $261,817,649 in 1945.

The land area irrigated increased from 999,410 ac. in 1910 to 1,165,100 ac. in 1948. In the Strawberry project, water is brought from the east side of the Wasatch mountains through a four-mile tunnel and used in the Utah valley 45 mi. away. Plans were developed to increase the irrigated land acreage to a total of 1,772,500 ac. Projects proposed with land acreages to be benefited are. (1) Bear river, 235,000 ac., (2) Weber basin, 99,000 ac.; (3) central Utah, 409,200 ac.; (4) Virgin river, 21,200 ac.; (5) miscellaneous areas, 249,900 ac.

The most important crop is hay. In 1949, 562,000 ac. produced 1,219,000 tons of hay (2.17 tons per acre), valued at $25,599,000. This includes both cultivated and uncultivated hay. Of wheat, the production of which had almost doubled since 1940, 428,000 ac. yielded 9,440,000 bu. (22.1 bu. per acre) valued at $16,520,000. Potatoes in 1949 yielded 3,003,000 bu. on 15,400 ac (195 bu per acre). Their value was estimated at $4,354,000. The 1949 crop of alfalfa seed, another important product, was valued at $4,557,000. Sugar beets had declined in importance, in 1949, 462,000 tons, as contrasted with 683,000 tons in 1939, were produced The yield per acre was 16.5 tons, as compared with 12.9 in 1939. The production of oats in 1949 on 45,000 ac. was 2,115,000 bu. (47 bu. per acre) valued at $1,692,000. In 1949, barley production amounted to 6,063,000 bu. on 129,000 ac. with a value of $6,063,000. In the same year field corn to the extent of 900,000 bu. on 25,000 ac. was valued at $1,395,000. Sweet corn for canning, 25,200 tons, was valued at $567,000.

Livestock on farms and ranges in Jan. 1950 was estimated at 1,333,000 sheep, 560,000 cattle, 88,000 swine, 58,000 horses and mules and 3,536,000 chickens and turkeys. The farm value of livestock in Jan. 1950 was estimated at $108,686,000. Livestock and livestock products sold during 1949 brought market receipts of $103,114,000. Butter production amounted to 5,485,000 lb. in 1948 as compared with 10,436,000 lb. in 1939. Milk production for 1949 was 669,000,000 lb. The wool (shorn) production for 1950 was 11,104,000 lb. Utah stood fifth in the nation in 1950 in sheep and wool production.

Mining.—In 1949 Utah ranked high among the states in output of the five major metals, having a total production valued at $121,649,828. In that year approximately 22,000 persons were employed in smelting and mining in Utah In value copper is the leading mineral, the 1940 production being worth $51,962,598;

in 1949 this figure had grown to $77,714,530. The lead production in 1949 was valued at $16,770,752, silver at $6,086,356, gold at $10,992,030 and zinc at $10,086,160. Utah is very rich in copper, silver, gold and zinc, but because of the fact that the ores are always found in combination, it was long impossible to recover a sufficiently high percentage of each to realize much profit on the state's resources. The invention of new selective flotation processes between 1915 and 1925 worked a mining revolution in Utah and sent its production skyward. The output of copper for 1949 was 197,245 short tons, second highest in the nation. Utah also ranked second in the production of molybdenum and silver. Output of silver for 1949 was 6,724,880 fine ounces. Only two states outranked Utah in the production of gold and lead in 1949, the state producing 314,058 fine ounces of gold and 53,072 short tons of lead in that year. Zinc production at 40,670 short tons was seventh largest in the union in 1949.

The most important nonmetallic mineral in Utah is coal, 3,524,000 tons being produced in 1940 and 6,716,000 tons in 1948. By 1950 in terms of production and employment, Utah led every state west of the Mississippi in coal mining. Nine-tenths of the coal produced in the state comes from Carbon and Emery counties. Salt, another valuable product, is obtained by means of solar evaporation of the salt brine deposits in the Great Salt Lake regions; 113,779 tons were produced in 1948. During World War I, when potash was in demand, potassium chloride was mined on the salt flats near the Nevada border. In 1948 about 60,000 tons of potassium chloride were produced in Utah and in 1950 Utah accounted for about 6% of the national production of potash. With the construction of the Geneva Steel plant near Orem, iron mining became an important activity, Utah in 1948 producing 3,233,413 tons. Native asphalt to the amount of 99,192 tons, valued at $1,987,049, was produced in 1947. By 1948 there were two plants producing gypsum products in the state. Mining and stock-piling of uranium was greatly expanded after World War II. The two principal centres were Marysvale in Piute county and Monticello in San Juan county. Vanadium is also processed in the Monticello area.

Forests and Lumbering.—Heavy spring floods have caused vast damage, especially where cutting has left the slopes exposed to erosion. The interests of irrigation also demand that the water be retained on these slopes as long as possible in the spring. Thus, though not so valuable commercially, Utah's forests are highly important as soil conservers.

Seven national forests covered 7,870,185 ac. in 1950 and contained 93% of the timber of the state. Their merchantable timber stand was estimated at 3,662,000,000 bd ft. The total merchantable timber stand was estimated at 4,170,000,000 bd ft. Injudicious cutting between 1880 and 1900 almost bared the western slopes of the Wasatch range near Great Salt lake. The cut in 1889 amounted to 14,000,000 bd.ft. and in 1899 to 18,000,000 bd.ft. Under regulation the output in the year 1949–50 was 33,324,000 bd ft., with a value of $1,766,000. Income of all sources from national forests almost covered costs of protection and management.

Manufacturing.—During and after World War II a great industrial expansion took place in Utah. In 1939 there were 560 manufacturing plants in the state which employed 13,843 persons. In 1947 there were 772 manufacturing establishments with 24,816 employees; these were paid $63,804,000 during that year. The value added by manufacturing was $128,298,000, compared with a corresponding figure of $43,341,000 in 1939. Next to food processing, in which the value added by manufacture amounted to $42,948,000, the most important industry was the primary metal industry with a value of $34,099,000 added by manufacture (1947). Paramount in the metal industry of Utah is the production of steel. The largest industrial establishment in the state is the integrated steel plant at Geneva, built and operated by the Geneva Steel company, a United States Steel corporation subsidiary, for the Defense Plant corporation. By 1950 it was capable of operating at an annual steel production rate of 1,800,000 tons. Production in 1949 was 918,700 tons of pig iron and 1,001,200 tons of steel ingots and castings. Other industries in 1947, with amounts of value added by manufacture, are as follows: petroleum and coal products, $12,222,000, printing and publishing, $9,390,000; chemicals and allied products, $5,112,000; stone, clay, and glass products, $5,627,000; fabricated metal products, $4,212,000, apparel and related products, $3,433,000; and machinery, except electrical, $3,215,000.

In 1947, 373 or 42.6% of the 772 manufacturing plants of the state were located in Salt Lake county. This compared with 84 for Weber county, 77 for Utah county and 34 for Cache county. Figures showing the number of plants employing 100 or more employees for these counties were as follows: Salt Lake, 23; Weber, 12; Utah, 7; and Cache, 2.

Transportation.—The Old Spanish trail, the Great Salt Lake trail and the Overland trail all aided in the early development of the state. The Union Pacific was the first railway and continued to be the dominating one, sending its branches into nearly every important mining or commercial centre. Other railways are the Denver and Rio Grande Western, Western Pacific, the Southern Pacific and the Los Angeles and Salt Lake, operated by the Union Pacific. At the beginning of 1950 steam railroads within the state operated over 1,973 mi. of track, while electric railroads used 160 mi. In 1950 5,454 mi. of road within the state belonged to the state highway system. Of this, 4,553 mi. were surfaced, either paved or gravelled. The mileage of local and county roads in 1950 was 22,995, of which 8,521 mi. were surfaced (37%). State road expenditures totalled $11,423,075.69 in the fiscal year 1950.

UTAMARO (1754–1806), one of the best known of the Japanese designers of colour prints, was born at Kawayoye. As a painter, his landscapes and drawings of insects are most highly considered by Japanese critics; but his fame will always rest among Europeans on his designs for colour prints, the subjects of which are almost entirely women—professional beauties and the like. The colour prints of Utamaro are distinguished by an extreme grace of line and of colour. His composition is superb; and even in his lifetime he achieved such popularity among his contemporaries as to gain the title Ukiyo-ye Chūkō-no-so, "great master of the Popular School." His work had a considerable reputation with the Dutch who visited Nagasaki, and it was imported into Europe before the end of the 18th century.

(E. F. S.)

UTE, a Shoshonean tribe of western Colorado and eastern Utah which gave its name to the latter state, and, with the Aztecs, to the great Uto-Aztecan family of Indians. The name was pronounced *Yoo-tah*, as preserved in the name of the state. Of the Utes, 1,900 remain.

UTICA, a city of ancient Africa, 15½ mi. N.W. of Carthage. The site of the town is covered with low-lying marsh lands. It was important as a commercial centre, and is mentioned in the commercial treaty of 348 B.C. between Rome and Carthage. Agathocles easily captured it in his expedition to Africa in 310. After the destruction of Carthage it received the rank of a *civitas libera* with an accession territory. After the battle of Thapsus in 46 Cato shut himself up in Utica for the final struggle against Caesar, and there committed suicide. Utica was the seat of a bishop from the 3rd century onward. It was captured by Gaiseric and the Vandals in 439, reconquered by the Byzantines in 534, and finally, in 698, it fell into the hands of the Arabs and was depopu-

lated Very little is left above the level of the ground In 1869 excavations revealed the fortifications, the acropolis, the quays of the commercial harbour and of the military harbour or Cothon; also the ruins of the amphitheatre, which was capable of holding 20,000 spectators, of the theatre, the baths, the reservoirs and the aqueduct which brought drinking water to the city.

UTICA, a city of central New York, U S A., the county seat of Oneida county; on the Mohawk river and the State Barge canal, 85 mi. from Albany, with a municipal airport. Pop. (1950) 101,531 The city covers 16.45 sq mi , with a mean elevation of 550 ft It is the seat of a state hospital for the mentally ill (1836) and the state Masonic home (1893) The total taxable assessed valuation of Utica for 1950 was about $153,000,000. The water supply (municipally owned) comes from the Adirondacks. Hydroelectric power is developed at Trenton Falls (15 mi N.). Utica's industrial plants number about 250; their annual payroll exceeded $50,000,000 a year, and their finished products were valued at more than $150,000,000 annually at mid-20th century. The city maintains first rank in New York state in the manufacture of cotton cloth and knit goods, and stands in the forefront in the manufacture of heating and ventilating apparatus Also produced are warm air furnaces, yarn, sheets and pillow cases, beds, springs, mattresses, cutlery, air compressors, sprayers, fishing rods and tackle, paper products, corduroy, plush and velveteen, emblems, men's and boys' clothing, rayon yarn, sportswear, metal stampings, pliers, nippers, pneumatic and electric tools, radios and other diversified lines.

The site of Utica was in the 22,000 ac. manor granted by George II. in 1734 to William Cosby and his associates. During the Seven Years' War a palisaded fort was built there, at the ford of the Mohawk, and named after Col. Peter Schuyler Later, when Ft. Stanwix at Rome was renamed Ft. Schuyler, the Utica fort was known by the name Old Ft. Schuyler. In 1792 Cosby's manor was put up for sale by the sheriff, and was bid in by Gen. Philip Schuyler, Gen. John Bradstreet, John Morin Scott and others, for £1,387 (about 15 cents an acre). After the close of the Revolution settlers began to come in, largely Palatinate Germans from the lower Mohawk. In 1786 the proprietors had the manor surveyed, and in 1788 an inn was built New settlers came, from New England, among whom in 1789 was Peter Smith (1768–1837), later a partner of John Jacob Astor, and father of Gerrit Smith, born there in 1797. In 1792 a bridge was built across the Mohawk. In 1798 the name "Utica" was chosen by lot from slips of paper in a hat. Utica's first charter as a village was obtained from the legislature in 1798, and on March 15, 1798, Oneida county was founded. The city was incorporated on March 1, 1832. By 1860 it had a population of 22,529, which grew to 33,914 in 1880 and 56,383 in 1900.

In the next two decades it increased 32% and 26·5% respectively, and between 1910 and 1925 the area within the corporate limits was more than doubled.

UTILITARIANISM, the form of ethical doctrine which teaches that conduct is morally good according as it promotes the greatest happiness of the greatest number of people (Lat. *utilis*, useful). The term "utilitarian" was noticed by J. S. Mill, in a novel of Galt; but it was first suggested by Bentham.

It is in a clerical work written against Hobbes, Bishop Cumberland's *De Legibus Naturae* (pub. in 1672), that we find the beginnings of utilitarianism.

Another clergyman, John Gay, in a dissertation added to Law's translation of Archbishop King's *Origin of Evil* (pub. in 1731) expanded Cumberland's doctrine. Further advances along the same line of thought were made by Abraham Tucker in his *Light of Nature Pursued* (pub. 1768–74). Gay and Tucker supplied nearly all the important ideas of Paley's *Principles of Moral and Political Philosophy* (pub. in 1785), in which theological utilitarianism is summarized and comes to a close. Hume's *Inquiry concerning the Principles of Morals* (pub. in 1751), though utilitarian is very far from being theological. Hume, taking for granted that benevolence is the supreme virtue, points out that the essence of benevolence is to increase the happiness of others.

Bentham, the founder of political utilitarianism, took up the greatest happiness principle not as an attractive topic of study, but as a criterion to distinguish good laws from bad. Sir John Bowring tells us that when Bentham was casting about for such a criterion "he met with Hume's *Essays* and found in them what he sought." These opinions are developed in his *Principles of Morals and Legislation* (pub. in 1789) and in the *Deontology* (published posthumously in 1834). Philosophically Bentham makes but little advance upon the theological utilitarians. His table of springs of actions shows the same mean-spirited omissions that we notice in his predecessors; he measures the quantity of pleasures by the coarsest and most mechanical tests; and he sets up general pleasure as the criterion of moral goodness. These principles of Bentham were the inspiration of the philosophic radicals of the early 19th century. From Bentham the leadership in utilitarianism passed to James Mill, who made no characteristic addition to its doctrine, and from him to John Stuart Mill whose essay *Utilitarianism* (pub. in 1863) sums up in brief and perfect form the essential principles of his doctrine. The last writer who, though not a political utilitarian, may be regarded as belonging to the school of Mill is Henry Sidgwick, whose elaborate *Methods of Ethics* (1874) may be regarded as closing this line of thought.

Even before the appearance of Sidgwick's book utilitarianism had entered upon its third or evolutional phase, in which principles borrowed from biological science make their entrance into moral philosophy. The main doctrine of evolutional or biological ethics is stated with admirable clearness in the third chapter of Darwin's *Descent of Man* (pub. in 1871). The most famous of the systematic exponents of evolutional utilitarianism is, of course, Herbert Spencer, in whose *Data of Ethics* (1879) the facts of morality are viewed in relation with his vast conception of the total process of cosmic evolution. The best feature of the *Data of Ethics* is its anti-ascetic vindication of pleasure as man's natural guide to what is physiologically healthy and morally good. Leslie Stephen with his brilliance but more attention to scientific method worked out in his *Science of Ethics* (1882) the conception of morality as a function of the social organism.

UTILITY. In economics the utility of a good is not conceived to be its usefulness, as judged by any objective standard, but its importance to a consumer. Capacity to excite desire rather than to yield benefits or bestow happiness is the measure of a good's utility, in this technical sense, and only as the conduct of life is completely rational and guided by adequate foresight are the two capacities the same.

The law or principle of *diminishing utility*, which serves in economics as a logical foundation for the laws of demand, is merely a general statement respecting an obvious aspect of the way in which men apportion their time and their means. Summarized, it is that progressively diminishing importance is attached by a consumer to successive additional increments of a good. Diminishing utility has two aspects: absolute and relative. One suit of clothes is more important than a second, and a second is more important than a third. It is more important that in a cold climate one should have coal enough to keep one room warm during the winter than that a second, or a third or a fourth room should be heated. It cannot be said, however, that

all luxuries and particularly such as minister to the "desire for distinction," have different uses which can be ranked in an order of diminishing importance.

Marginal utility is the utility of the last increment (not necessarily last in point of time) which the consumer thinks worth acquiring (*See* also ECONOMICS and VALUE) (A. Yo.)

UTMAN KHEL, a Pathan tribe who occupy the hills to the north of Peshawar in the North-West Frontier Province of India. They claim to be descendants of Baba Utman, who accompanied Mahmud of Ghazni in his expedition into India in 997 The Utman Khel are a tall, stout and fair race, but in dress and general customs follow the neighbouring peoples of Bajour.

UTO-AZTECAN FAMILY, perhaps the most numerous and important stock of North American Indians, is named after a representative northern and southern tribe, and it extended in a long irregular tract, broken only in Arizona, from Idaho to Tabasco, Mexico, and beyond as far as Panamá in scattered populational islets The bond of union was linguistic and geographic, not racial or cultural In customs there is little common to the lowly northern tribes and the barbarically advanced ones of southern Mexico. The organization is as follows, tribes separately treated being asterisked — I, Shoshonean sub-family: (*a*) Pueblo branch, *Hopi; (*b*) Plateau branch, comprising 1, *Ute, southern *Paiute, Chemehuevi, Kawaiisu; 2, *Shoshone *Comanche, Gosiute, Panamint; 3, Bannock, northern *Paiute (Paviotso). *Mono; (*c*) Kern river branch, Tubatulabal; (*d*) southern California branch, comprising 1, Serrano, 2, *Gabrielino, 3, Luiseño, Cahuilla, Juaneño, Cupeño II Piman or Sonoran sub-family: *Pima, *Papago, Sobaipuri, *Tarahumare, Opata, Mayo, *Yaqui, Tepecano, Tepehuane; Cora, *Huichol, etc III. Nahua (*see* NAHUATL) sub-family, in which the *Toltec and *Aztec were most conspicuous. (A. L. K.)

UTOPIA, an ideal commonwealth whose inhabitants exist under perfect conditions. Hence *Utopian* is used to denote a visionary reform, which fails to recognize defects in human nature The word first occurs in Sir Thomas More's *Utopa*, published in Latin as *De optimo Reipublicae statu, deque nova insula Utopia* (Louvain, 1516) It was compounded by More (*q.v.*) from the Greek *ou*, not, and *topos*, a place, no-where

The idea of a Utopia is, even in literature, far older than More's romance; it appears in the *Timaeus* of Plato and is fully developed in his *Republic*. The idealized description of Sparta in Plutarch's life of Lycurgus belongs to the same class of literary Utopias. A similar idea occurs in the Greek, and the mediaeval Norse, Celtic and Arab legends which describe an earthly paradise in the western or Atlantic ocean (*see* ATLANTIS). Few of these survived after the explorations of Columbus, Vasco da Gama and others in the 15th century; but in literature More's *Utopia* set a new fashion: the imaginary voyager arrives at the ideal state In Bacon's *New Atlantis* (1624–29) science is the key to universal happiness; Tommaso Campanella's *Civitas Solis* (1623) portrays a communistic society; James Harrington's *Oceana* (1656), which had a profound influence upon political thought in America, is a treatise rather than a romance, and is founded on the ideas that property, especially in land, is the basis of political power, and that the executive should only be controlled for a short period by the same man or men. With these may be compared the Christian Utopias, J V. Andreae's *Christianopolis* and S. Golt's *Nova Solyma* (1648). Bernard de Mandeville's *Fable of the Bees* is unique in that it describes the downfall of an ideal commonwealth. Other Utopias are the "Voyage en Salente" in Fénelon's *Télémaque* (1699), Vairasse's *Histoire des Sevarambes* (1716); Mercier's *L'An 2440* (1742); James Burgh's *Account of the Cessares* (1764); J. B. Say's *Olbie* (1800); Etienne Cabet's *Voyage en Icarie* (1848); Bulwer Lytton's *The Coming Race* (1871); Samuel Butler's *Erewhon* (1872) and *Erewhon Revisited* (1901); Edward Bellamy's *Looking Backward* (1888); William Morris's *News from Nowhere* (1890); H. G. Wells's *Anticipations* (1901), *A Modern Utopia* (1905) and *New Worlds for Old* (1908). Many Utopias, like the *Fable of the Bees* and *Erewhon*, are satires. Others are inspired by socialistic ideals; among these may be mentioned *Freiland, ein soziales Zukunftsbild* (1890) and *Reise nach Freiland* (1893), by the Austrian Theodor Hertzka (b. Budapest, 1845), portraying a commune in Central Africa.

UTRECHT, the smallest Netherlands province, has the Zuider Zee washing its very short northern frontier. Its area is 526 sq mi, and with a population of 406,960 (1930) it ranks third in the list of most densely-populated provinces This is also the position which it occupied at the beginning of the 20th century, but between 1900 and 1930 its average density increased from 470 per sq mi to 773 per sq. mile. Utrecht city (*q.v.*) has (1930) 154,882 inhabitants (fourth in the country) and Amersfoort over 38,500 The other settlements are relatively small.

The province falls entirely within the Rhine delta. (*See* HOLLAND: *Coast and Relief*) The southern limit of the Scandinavian ice passed diagonally through the province from northwest to southeast in the vicinity of Utrecht city, and the western part of the province consists of clay lands and, in the northwest, of low fen

The sand and gravel eastern region is covered with bare heaths and patches of woods, and the occupations of the scanty population are chiefly those of buckwheat cultivation and peat-digging. Amersfoort is here the only large town, but along the western edge of this tract there is a row of thriving villages, such as Amerongen, Driebergen, Doorn and Zeist

The southern area is picturesque with more extensive woodlands and has long been popular for country seats: Zeist provided a hunting-box for William III, and Doorn a retreat for ex-Kaiser Wilhelm II Veenendaal, on the south-eastern border, is a market for the local bee-keeping industry. Amersfoort, one of the chief seats of the Old Catholics, is now a thriving garrison town, with a variety of crops, including tobacco, growing on the sandy hills in its neighbourhood. It retains the Koppelpoort spanning the Eem, a gateway which is probably the finest and least altered mediaeval entry to any town in the Netherlands Within the town the old ramparts are now laid out as leafy promenades Baarn, farther downstream, is a popular summer resort for Amsterdam citizens, and on the east side of the Eem are the typical peaceful fishing villages of Bunschoten and Spakenburg.

At Maarsen, near Utrecht, is situated Zuylen castle, which is of some note. Rhenen was once the seat of an independent lordship, though afterwards joined to the bishopric of Utrecht. The ancient church has a fine tower (1492–1531) Wijk-by-Duurstede, originally a Roman settlement, was of considerable commercial importance as early as the time of Charlemagne, but decayed owing to Norman raids in the 10th century. The tower of the ruined castle of the bishops of Utrecht still stands.

Ecclesiastical History.—The province represents the bulk of the ancient see, founded in 722 by St Willibrord The bishopric was weak compared with Holland, Gelderland and Brabant, and the middle ages saw local wars. Holland's growth in the 14th century forced Gelderland and Brabant to relinquish their claims over the see Later, in the 15th century, her supremacy passed to the dukes of Burgundy and, still later, to the emperor Charles V. Notwithstanding the elevation of Utrecht to an archbishopric (1559), it was one of the seven provinces on the Protestant side which signed the Union of Utrecht (1579) against Spain. The chapter of the see was secularized and the power of the members of the five ecclesiastic colleges was severely curtailed Under the vicariate of de la Torre (1651), trouble began with Rome, which claimed the right of appointing successors It started in 1702 when Codde, the nominee of the Dutch secular clergy, was accused by the Jesuits of Jansenism (*q.v.*). Although innocent, he was deposed, and his chief opponent, de Kock, was appointed in his stead De Kock was expelled from the country by the States-General and the Church of Utrecht was without a head.

In 1713 the French Government enforced the bull *Unigenitus*, and in the following years many refugee priests entered Holland, including Dominique Varlet who settled in Amsterdam in 1720. Steenoven, in 1723, was elected archbishop by the chapter of Utrecht and his subsequent consecration by Varlet led to a general excommunication by the pope. The Jansenist Church of Holland has continued as an independent body accepting the general councils, but rejecting *inter alia* the Vatican council and the infallibility

of the pope. Two suffragan sees were created. Haarlem (1742), Deventer (1757); and though, in the following century, the Church lost membership, yet it has recently attracted numbers of the less rigid Roman Catholics At first the Jansenist church of Utrecht established close relations with the Old Catholic movement in Germany, but it subsequently viewed with strong disapproval the departures of the German members from Catholic tradition. The Jansenists refused to recognize the validity of Anglican orders, and in 1908 a singular offshoot of the Church of Utrecht was established in England when Dr. Gerard Gul (Jansenist archbishop of Utrecht) consecrated Arnold Harris Mathew, bishop of the Old Catholics in England. Meanwhile, in 1851, in Holland itself the Roman Catholic hierarchy had been restored, with Utrecht as the archiepiscopal see.

For general statistics see HOLLAND.

UTRECHT, a city of Holland, capital of the province of Utrecht, on the Crooked Rhine, which here divides into the Old Rhine and the Vecht. Pop. (1930), 154,882. It is the most important junction station of Holland, 22 mi. S SE. of Amsterdam by rail. It is a picturesque old town. The line of the ancient ramparts, demolished in 1830, is now only marked by the Singel, or outer canal, which surrounds the oldest part of the city, with gardens and promenades laid out on the inside. Two canals, the Oude and the Nieuwe Gracht, intersect the town from end to end. Utrecht is the seat of a university, and of a Roman Catholic archbishopric. It is also the seat of the archbishop of the Dutch Old Catholics. The Domkerk, dedicated to St. Martin, is a large Gothic building erected in 1254–1267 on the site of the original church founded by St. Willibrord about 720 and completed by Bishop Adelbold about 1015. An open space forming the heart of the square in which the church stands separates the solitary western tower (14th century) from the choir and transept, the nave having been blown down by a violent hurricane in 1674 and never rebuilt. In the crypt are preserved the hearts of the German emperors Conrad II (1039) and Henry V (1125). The Roman Catholic cathedral of St. Catherine dates from 1524 and has been restored in modern times. Other churches of very early foundation in Utrecht are the Pieterskerk and the Janskerk. Attached to the Domkerk by fine old Gothic cloisters is the university, which was founded in 1636 and enlarged in 1894.

Connected with the university are a valuable library, occupying the palace built for Louis Bonaparte, king of Holland, in 1807, and containing upwards of 200,000 volumes and mss ; a museum of natural history; a botanic garden; an observatory, etc. The archiepiscopal museum (1872) contains examples of all branches of sacred art in the Netherlands. In the Museum Kunstliefde is a small picture-gallery, chiefly remarkable for some pictures by Jan Scorel (1495–1562); the museum of antiquities contains a miscellaneous collection. Other buildings of interest are the museum of industrial art; the so-called "Pope's house," built in 1517 by Adrian Floriszoon Boeyens, afterwards Pope Adrian VI, and a native of Utrecht; the royal mint of Holland; the Fleshers' Hall (1637); the home for the aged, occupying a 14th-century mansion, and the town hall (1830).

The country round about Utrecht is pretty and plentifully studded with country houses, especially on the road to Arnhem. Close by, on the northeast, is the residential suburb of De Bilt, the seat of the Dutch meteorological institute. Four miles northwest of Utrecht stands the 13th-century castle of Zuilen, which was carefully restored in 1752, and is still in excellent preservation. Five miles east of Utrecht is the town of Zeist, the seat of a Moravian settlement established here in 1746 There are also a fine castle (1667) and grounds, a sanatorium for children and numerous modern villa residences. At Ryzenburg, close by, is a Roman Catholic seminary, founded in connection with the establishment of the Roman Catholic hierarchy in 1853 and practically serving as an archiepiscopal palace.

History.—Utrecht (*i.e.*, *Oude Trecht* or Old Ford, rendered in Latin documents *Vetus Traiectum*) is a city of great antiquity. The place is mentioned in the itinerary of Antoninus, but its importance began when St Willibrord (*q.v.*), the apostle of the Frisians, established his see there. The bishop's seat had to be fortified against the incursions of the heathen Frisians and Northmen, and the security thus afforded attracted population till, after the destruction of its rival Dorestad by the Normans in the 9th century, Utrecht became the chief commercial centre of the northern Netherlands. On the accession of Bishop Balderic (A D 918–976) to the see, Utrecht had just been sacked by the Northmen He succeeded in driving the raiders away, rebuilt the walls, and during the 58 years of his episcopate the town grew and prospered. Its gradual acquisition of civic rights followed the same line of development as in the German episcopal cities. Bishop Godebald (1122–1127) granted to the inhabitants of Utrecht and of Muiden, the neighbouring port on the Zuider Zee, their first privileges, which were confirmed (June 22, 1122) by the emperor Henry V. The magistrates, the *Schout* or high bailiff and his assessors, the *Schepenen* (*scabini*, *échevins*), were nominated by the burgrave from the order of knights. In 1196 we read for the first time of councillors as assessors of the magistrates, but these, who a little later were known as the *Raad* or council, were also nominated. As the 13th century advanced, the council, representing the wealthy and powerful gild of merchants, began to take a larger share in the government, and to restrict more and more the direct exercise of the episcopal authority.

The struggle between the town of Utrecht and its ecclesiastical sovereign reached its climax (1481–84) in the "groote vorlag," or great quarrel, between the citizens and Bishop David, the Bastard of Burgundy With the aid of John, burgrave of Montfoort, who had been called in, and endowed with supreme power for the defence of the town, the Utrechters defeated all the efforts of their bishop, aided by the Hollanders and an aristocratic faction. They only succumbed when the weight of the archduke Maximilian was thrown into the scale against them (1484). The struggle continued with intermissions till 1527 when Bishop Henry of Bavaria sold his temporal rights to the Emperor Charles V Utrecht took a leading part in the revolt of the Netherlands The union of the seven northern provinces, proclaimed at Utrecht in 1579, laid the foundation of Dutch independence (*see* NETHERLANDS) After the death of William the Silent, the Utrechters, jealous of the influence of their old enemies the Hollanders, elected a stadtholder of their own. The Roman Catholics had but little influence on the city, where the aristocrats inclined to the moderate (libertine) opinions advocated by the preacher Hubrecht Duifhuis, while the democrats were organized in the new church order introduced by the uncompromising Calvinist Petrus Dathenus (d. 1581). After the advent of the earl of Leicester as governor-general of the Netherlands in 1585, the previous dominance of the aristocrats was broken and the ultra-Calvinistic Adolph, count of Nuenar, who was elected stadtholder, placed the people in power. The English governor-general made the town his headquarters during residence in the Netherlands, and took it under English protection. His withdrawal from the Netherlands was followed by the return of the aristocratic party to power. From this time until the French Revolution, the democratic institutions of the city remained only a name.

UTRECHT, TREATY OF, the general name given to the important series of treaties which in 1713 and 1714 concluded the War of the Spanish Succession (*q.v.*).

The congress opened on Jan. 29, 1712. But it was not until July 10, 1712, that King Philip of Spain signed a renunciation of his rights to the succession of the crown of France. Then, England and France having concluded a truce, the pace was quickened and the main treaties were signed on April 11, 1713.

By the treaty between England and France Louis XIV. recognized the Protestant succession in England and undertook to give no further aid to the Stuarts. France ceded to England, Newfoundland, Nova Scotia or Acadia, the island of St. Kitts or St. Christopher, and the Hudson's bay territory, and promised to demolish the fortifications of Dunkirk.

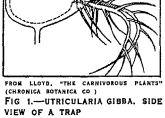
The treaty between France and the United Provinces was mainly concerned with securing the barrier of fortresses. These arrangements were somewhat complicated and to a large extent provisional, as Austria and Bavaria, two countries deeply interested in the fate of the Netherlands, had not yet assented to

the terms of peace. By a commercial treaty concluded on the same day, France gave the Dutch privileges similar to those enjoyed by England. Other treaties concluded at the same time were between France and Savoy, France and Prussia, and France and Portugal By the first the duke of Savoy regained Savoy and Nice, and France undertook to obtain for him the island of Sicily and the title of king. By the second Prussia secured some small additions of territory, including part of Gelderland and Neuchâtel; in return France definitely and finally obtained the principality of Orange. The treaty between France and Portugal mainly concerned the Portuguese settlements in Brazil, her claim to these being recognized by France.

Other treaties were signed at Utrecht between Spain and the allies, Philip now concluding these as the recognized king of Spain. On July 13, 1713, a treaty was signed between England and Spain, which embodied certain commercial arrangements previously made between the two countries, Spain ceded to England Gibraltar and Minorca, and promised to give up Sicily to Savoy. She gave also to England the monopoly for 30 years of the lucrative slave trade with Spanish America, hitherto enjoyed by France: this was the famous Asiento treaty. The peace between Spain and the United Provinces was signed on June 26, 1714, but the conclusion of that between Spain and Portugal was delayed until the following February. The former was concerned mainly with commercial matters, Spain giving the United Provinces most-favoured-nation treatment.

The treaty of Utrecht also provided compensation for the Emperor Charles VI as soon as he surrendered his claim to Spain. He was to receive Naples and Milan, and also the Spanish Netherlands, henceforward known as the Austrian Netherlands

But the general pacification was still incomplete, as France and the empire continued at war. It was not long, however, before Charles VI realized that without allies he was no match for France.



Accordingly, his representative, Prince Eugène, met the French marshal Villars at Rastatt in Nov. 1713, and here peace was made on March 7, 1714, Charles VI concluding the treaty without waiting for the assent of the states of the empire. This consent, however, was necessary, and a little later the representatives of some of the princes of the empire met those of France at Baden, where, on Sept. 7, 1714, the treaty of Baden, the last of the treaties included in the general peace of Utrecht, was signed. This dealt entirely with the question of the frontier between France and the empire, which was restored as it was before the war except that France gained Landau.

One other important matter was dealt with at Utrecht. A second barrier treaty between England and the United Provinces was signed on Jan. 30, 1713, and a third treaty signed at Antwerp on Nov. 15, 1715 clinched the matter. Seven fortresses were to be garrisoned by a total of 35,000 men, three-fifths of the cost being borne by the imperial government and the remainder by the United Provinces

The treaties were bitterly assailed by the Whigs, and after the accession of George I four of its Tory authors, Bolingbroke, Oxford, Ormonde and Strafford, were impeached for concluding it, the charges brought against them being that they had corresponded with the queen's enemies and had betrayed the honour and interests of their own country.

BIBLIOGRAPHY.—The text of the treaty of Utrecht is published as the *Actes, mémoires et autres pièces authentiques concernant la paix d'Utrecht* (Utrecht, 1714–15); and by C. W von Koch and F. Scholl in the *Histoire abrégée des traités* (1817–18). As far as it concerns the party politics of England, there is much about the peace in Dean Swift's works. *See* also C. Giraud, *La Paix d'Utrecht* (1847), I S. Leadam *Political History of England 1702–1760* (1909); A. W. Ward in the *Cambridge Modern History*, vol. v (1908), and the *State Trials* for the proceedings against the impeached English ministers. But perhaps the most valuable work on the whole peace is O. Weber's *Der Friede von Utrecht. Verhandlungen zwischen England, Frankreich, dem Kaiser und den Generalstaaten 1710–1713* (Gotha, 1891).

UTRICULARIA, A genus of the family Lentibulariaceae containing about 150 species, all carnivorous ("insectivorous") Closely related are the genera *Biovularia* (2 species) and *Polypompholyx* (probably four species). They are commonly called "bladder-worts" because of their numerous small hollow traps, first regarded as bladders and thought, erroneously, to serve for floating the plant. Since land forms also have "bladders," this view was obviously open to question, and was shown to be false. These plants live either submerged, usually in still fresh waters, though two species are known which live attached to stones or other firm surfaces in rapidly running streams.

FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

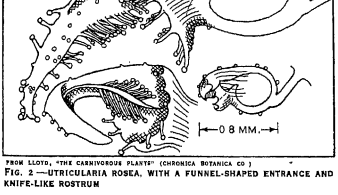


FIG 1.—UTRICULARIA GIBBA. SIDE VIEW OF A TRAP

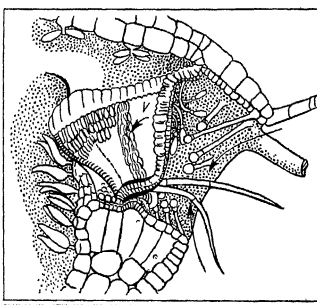
In the latter the traps are, literally, streamlined, and are thus adapted to moving water. Or they grow in wet soils, usually of quartz sand or mud, or in wet moss or creeping on leaves in wet jungles. Some species take intermediate stations, growing either in the water or on wet mud One or two species grow in the water held by the leaf rosettes of certain epiphytic bromeliads (related to the pine-apple) in South America They are of world-wide distribution, from Greenland to Australasia and around the globe in both latitudinal hemispheres. North America has about a dozen species including a number of land forms (*e g*, *U. subulata*). Europe has about four species, all submersed or partly submersed forms. The largest common to both hemispheres in the temperate regions is *U. vulgaris*. Floating in quiet waters, this attains a length of 3 ft. or more, with several branches and with finely dissected leaves bearing the numerous traps, 2–3 mm. long, which serve to catch minute animals, such as water-fleas (Crustacea), larvae of flies, including mosquitoes, small spider-like creatures, etc.

It is a common experience to find minute algae (*e g.*, *Euglena*) living apparently happily within the traps. The prey serves as a source for nitrogenous food, and probably for salts of various kinds.

A few land forms are of considerable stature, as *U. globulariaefolia*, of Trinidad and *U. remifolia*, with large showy flowers, of the Organ mountains of Brazil. The latter is showy enough to be grown in greenhouses, where it is usually segregated with the orchids, less for its superficial resemblance than for its similar requirements of high humidity and temperature. But the vast majority of land forms are small and very inconspicuous save for their flowers which, though often small, are quite readily seen The larger, though having small vegetative parts, have tall inflorescences, the flower stalks in *U. cornuta* being a foot high. The smaller are inconspicuous among the mosses, etc., in which they grow, except for their showy, small flowers. Still others are almost microscopic in size.

The plant's body consists of a more or less horizontal stem (a



FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

FIG. 2.—UTRICULARIA ROSEA, WITH A FUNNEL-SHAPED ENTRANCE AND KNIFE-LIKE ROSTRUM

stolon) bearing simple or divided leaves placed in a variety of relations, not following any obvious rule A peculiar and significant feature, noted by Karl Goebel, is that the leaves face away from the apex of the stolon which bears them, the reverse of the usual condition. Correlated with this is the occurrence of the axial bud in a correspondingly reversed position

In *Utricularia* the calyx has two members, a dorsal and a ventral one. In *Polypompholyx* there are two additional, in lateral positions. The corolla is entire and two-lipped, of the personate type, with the mouth closed by a palate, and provided with a spur from the lower moiety. The spur is very large in *U. menziesii* and vestigial in *U. minor*, and is represented by a wide poculate expansion in *U. cymbantha*. The spur is a nectary, but nectar glands occur also in the bowl-shaped condition. The colour of the corolla may be white, very often yellow, pale blue to purple, and in one species, brilliant crimson, variously marked on the palate with other colours. Reproduction is by means of seeds, by winter or resting buds and by adventitious growth from various parts, as from leaf buds The inflorescence is a raceme, and in some floating kinds, is held up in position by means of a whorl of floats, which are leaves in which the midrib is much inflated, as in the American *U stellata*. Expansions of the stolons lead to the formations of tubers, which, containing sap and starch, can serve to tide over dry periods and for reproduction

But the most noteworthy feature of all three genera here considered is the occurrence of traps, usually, but hardly correctly, called bladders From the time of Darwin and Ferdinand Cohn (1875) until that of Frank Brocher (1911) they were thought to be passive traps, consisting of a hollow, bladder-like sac guarded by a curved, flexible door or valve. This, it was interpreted, would be pushed in by an intrusive animal of suitable size, and permit easy entrance; but since the valve is a check valve, permitting movement in only one direction, the animal remained captive, balked of escape by a now resisting wall This idea was shown to be quite inadequate by Brocher, a Swiss entomologist,

FIG. 3.—UTRICULARIA GIBBA

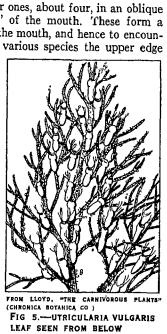
Diagram of the entrance in longitudinal section. The outer surface of the door and the sides of the entrance bear mucilage glands. The arrows point at the tripping bristles and indicate the direction of the prey's approach. V indicates Velum

who, during a study of mosquitoes and utricularia in relation to each other, discovered that, when a larva is caught, the sides of the trap, erstwhile inpressed and concave, were then definitely expanded This could be explained only as the result of an inflow of water, and that the prey was washed into the trap thereby This indicated that the valve or door was fixed in a position of unstable equilibrium which was upset by impact of the prey on certain bristles, four in number, projecting from the door surface

This was later confirmed (E. M. Merl, Th. Czaja) and it was shown also that the action could be repeated, 14 repetitions of the action having been counted. This could be explained only when it was discovered that the wall of the trap constantly excretes water from the inside of the trap to the outside and that the door is so postured that it can resist the relatively increased water pressure on the outside Later it was found that the door posture of itself is insufficient to render it watertight, which it must be to allow the maintenance of reduced water pressure on the inside. It was then found that, in addition to the door, there is a second valve, the "velum," which consists of a membrane attached to the valve seat on which the door edge rests, applied against the lower zone of the door in such manner as to prevent the inleakage of water under it, as can readily occur at the side reaches of the door edge (F. E. Lloyd). The valve seat, called by Darwin the "collar," is a stout, curved weal of tissue, lined with a soft cellular lining, the cells of which supply the velum by exfoliation of their cuticles, which remain attached to each other and to the front edge of the collar. After action, the valve or door reseats itself on the upper surface of the collar, and the velum folds upward over the door edge. The trap is then sealed, and, after sufficient excretion of the inner water, will again react.

FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

FIG. 4.—UTRICULARIA GIBBA: THREE STAGES IN CAPTURE OF PREY



Above, door being sprung by larva. Middle, door opening. Below, larva caught and door again closed

In order to set the trap into action, the door is provided with a trigger mechanism. In *U. vulgaris* and the like, this consists of four to six stout, curved bristles which, when disturbed by the impact of prey, bend, and in doing so, twist slightly the edge of the door, releasing it from its delicate equilibrium, and allowing the external water pressure to push it in, carrying the prey with it. The inward swing of the door is followed, as the pressure of the insurging water decreases, by a return to approximately the original posture, the whole occupying about one thirty-fifth of a second. The walls of the trap are now more or less bulging, due to the greater contained volume of water. The trap is now in the relaxed state. The set state is reached in 15 to 30 minutes (*U. vulgaris*), during which time the door changes its posture somewhat, because of the now increased water pressure, and is again ready for repetition. As the result of somewhat different mechanical conditions in the traps of many species, the change in posture of the door from the relaxed to the set state is very marked and readily observed (*U. capensis; Polypompholyx.*)

The excretion of water from the inside to the outside of the trap through the walls demands a mechanism, and this is found in two sets of trichomes, one on each surface, whose capital cells are bare of cuticle. These are, on the inside, the quadrifid and bifid hairs, as Charles Darwin called them, and on the outside hairs with rounded or elongated capitals. Since the rest of the wall surfaces are covered with cuticle, this seems to be the only reasonable conclusion. The quadrifid hairs are numerous in *U. vulgaris*, and few, but relatively much larger in small traps such as those of *U. subulata.*

The trigger mechanism is widely different in various species, but is always composed of trichomes of various shapes and dispositions. Aside from these, the remaining appendages of the trap consist of variously shaped and disposed emergencies, rang-

ing from branching arms to extensive wings. In *U vulgaris* there are two curved arms extending from the upper corners of the entrance Between them on the edge of the entrance stand several delicate, long bristles, with similar ones, about four, in an oblique row extending along the "cheek" of the mouth. These form a sort of guiding funnel leading to the mouth, and hence to encounter with the trigger bristles In various species the upper edge of the entrance may be strongly developed into a single, or a bifurcate rostrum, armed with large glandular trichomes The single rostrum may be broad and rounded, or may have the shape of a knife blade. Again, a rostrum may arise from the lower edge of the entrance and extend far forward and upward, as in the American *U. purpurea*. In Australian species, the rostrum may be much branched and in such case the trap bears two ventral wings extending obliquely toward the entrance and acting as guides thereto. Again, the whole margin of the entrance may be drawn out to form a deep funnel lined with radiating rows of glandular hairs, which it has been suspected secrete, beside mucilage, some substance or substances attractive to prey, thus acting as a lure. Convincing evidence is, however, lacking.

FROM LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

FIG 5.—UTRICULARIA VULGARIS LEAF SEEN FROM BELOW

The genus *Polypompholyx* has traps which have thick and massive walls three in number, so that the trap is triangular in section. The entrance is blocked in front by a swelling of the stalk, so that approach to it must be made from the sides. Wings and rows of bristling hairs serve to guide the prey appropriately. These plants are all found in central south and southwestern Australia.

Biovularia has two species, one in Cuba and one in South America. They are characterized by the possession of only two ovules, in contrast to the 100 or more of *Utricularia*. Certain species of Africa, because of the fact that only three ovules occur, have been regarded as belonging in *Biovularia*, but the traps are like those of *Utricularia*. Those of *Biovularia* have six tripping bristles set at about the middle point of the door instead of near the lower edge, as in *Utricularia*.

It is not satisfactorily determined whether the dissolution of captured organisms in the traps is the result purely of secreted enzymes, of bacterial action, or both. Much of the difficulty of deciding the question arises from the small size of the traps.

See F. E Lloyd, *The Carnivorous Plants* (1942). (F. E. L.)

UTTAR PRADESH: *see* UNITED PROVINCES.

UTTOXETER, a market town of Staffordshire, England. Pop. of urban district (1951) 7,440. Area, 5.2 sq.mi. The town lies on high ground near the river Dove. The boundaries were extended in 1934. Uttoxeter (Wotocheshede, Uttokeshather, Utcester, Uttoxater) belonged to Algar, earl of Mercia; at Domesday it was held by the king; later it passed to the Ferrers family and in the 12th century Earl Robert constituted Uttoxeter a free borough.

Uttoxeter, with the rest of the honour of Tutbury, escheated to the crown in 1266; it was regranted to Edmund Crouchback, and belonged to the duchy of Lancaster until 1625. In 1308 Thomas, earl of Lancaster, obtained the grant of a fair on the vigil, day and morrow of St Mary Magdalene The market was the greatest in that part of England for cattle and provisions. The market place was remodelled in 1935. The church of St. Mary has a fine Decorated tower and spire. Alleyne's grammar school was founded in 1558. At Denstone, 5 mi. N., is Denstone college (1873). Industries include the making of biscuits, agricultural implements and condensed milk.

UVALDE, a city of south central Texas, U.S.A., the county seat of Uvalde county, located about 85 mi. S W of San Antonio. It is served by the Missouri Pacific and the Southern Pacific railroads, by U S. highways 83 and 90 and by state highway 55. Pop. (1950) 8,674; (1940) 6,679

Uvalde's principal industries include the production of honey, sheep, goat and cattle ranching, dry and irrigated farming. There are asphalt mines near by.

Juan de Ugalde, an 18th century Spanish soldier, gave his name to Uvalde, although the *g* in his name was replaced with a *v*. Settlement began in the city about the middle of the 19th century.

UXBRIDGE, market town and urban district of Middlesex, Eng., 15¼ mi. from London by the G.W.R. and the London Passenger Transport board. Pop. (est. 1951) 55,944. Area, 16 sq.mi. Near the Grand Junction canal are sawmills, and wharves for timber, coal and slates. There are also flour mills, a brewery and engineering works. Uxbridge is said to date from Alfred the Great, but is not mentioned in Domesday Here negotiations were begun, on Jan. 30, 1645, between the commissioners of Charles I and the parliament, but were broken off on Feb 22. A part of the "Treaty House," in which they were carried on, remains. In 1647 the parliamentary headquarters were in the town. It remained a garrison town until 1689 It was granted a market by Henry II. There are two fairs

UXBRIDGE, a town of Worcester county, Massachusetts. Pop. (1950) 7,005; 1940 federal census 6,317 It is in a picturesque region of low hills and small lakes. The principal industry is the manufacture of woollen goods

Uxbridge was divided from Mendon and incorporated as a town in 1727.

UXMAL, the ruins of an ancient Mayan capital city of the new empire about 50 mi. S. of Merida, in Yucatan, Mexico; in 89° 42′ W. and 20° 18′ N. It was one of those frontier Mayan cities that did not rise to prominence until shortly before A D. 1000 when the League of Mayapan was formed with three cities, Mayapan, Chichen-Itza and Uxmal, dominant in "the New empire" of the Mayas. With the earlier fall of the Old empire in Guatemala and southern Mexico the Itza established themselves at Chichen (The Mouths of the Wells), the Cocom made Mayapan their capital, and the Tutul Xiu, a kindred tribe, settled at Uxmal. The period subsequent to the formation of the League of Mayapan constitutes the golden age of the New empire of the Mayas, when peace and plenty provided favourable opportunity for the development of trade and religion and science and art, particularly architecture.

Great stone temples and colonnades elaborately carved and ornamented rose in every city; religion flourished; the sciences, especially astronomy and mathematics, were fostered; and a renaissance of culture held sway for over two centuries. The buildings of this period at Uxmal surpassed those of the other cities in their grandeur and elegance. When the New empire crumbled under internal dissension and the conquest of the Aztec-Toltec imperialists from central Mexico, about the middle of the 15th century, Uxmal succumbed with the rest, and it is reasonably certain that only vagrant tribes lingered about the old ruins at the time of the Spanish conquest.

The region of the Uxmal ruins, like most of Yucatan, is a dry grass savanna, in places rather heavily wooded as about Uxmal. The relief is negligible, the terrain for the most part being as level as a floor, though a range of low hills lies between Uxmal and Ticul, the railway station about 20 mi. eastward. The water-supply of the city was furnished by "cenotes," or wells, within the city, or by pools some distance to the west, now partly filled up and vanished, but in the rainy season so marshy as to be the breeding-places of myriad mosquitoes that spread malaria, fever and disease. It may have been some of the mosquito-borne pestilences that destroyed the Mayan civilization.

The main ruins occupy an area not much over 160 ac., but outlying remnants indicate a residential district much larger, for which the central group, massive and extremely impressive, merely constituted the religious and civic nucleus. The stone used in the structures is the pale, yellowish and reddish-gray limestone, obscurely marbled, which was probably obtained not far from the

city, though the quarry has not yet been definitely located The body of the walls and the framework of the temples is generally of fragmental stone set in a whitish mortar of excellent composition made of lime burned in the neighbourhood. The facings and ornaments are all cut exquisitely yet daringly, and in view of the fact that the Mayan artisans laboured without metal tools, the excellence of their work is amazing The faces and edges are graved and hewn with perfect precision and the joints are in many cases so perfect as to conceal the mortar Much plastering was done, and nearly all surfaces, and apparently even the intricate details of mouldings and sculptures, were smoothed painstakingly by white plaster and finished in many colours

The walls are massive, averaging 3 ft. in thickness, but in some ruins 9 ft , approximately vertical on the exterior to the full height, and to the spring of the arch inside Few recesses or projections disturb the smoothness of the exterior walls, but elaborate ornamentation relieves the monotony. Rigid mouldings divide the walls into upper and lower zones, the latter faced with smooth stone except for a narrow band of design near the base, and the former, a development of the entablature, compositely graven and bordered by a heavy band of mouldings at the top. The shoe-shaped coping stones held the level cement roof. The corners of the buildings were square or rounded. No windows or other openings admitted air or light (or mosquitoes) The doorways, confined to the lower panel of the wall, were simply constructed and of medium to large size The jambs were faced with cut stone and the longer lintels were of zapote wood dressed square or partially so.

The buildings were generally long rectangular with one, or more usually two, ranges of rooms; and as a rule these buildings were arranged in groups of four forming a quadrangle. None of the buildings was over one story in height, and nearly all were built on terraces or pyramids of varied ground plan and profile The rooms were high and spacious, with vaulted ceilings formed of the usual wedge-shaped arch built from horizontally laid stones corbelled and bevelled with the slope Stairways were numerous, wide, steep and well built of cut stone.

Five principal buildings or groups of structures were the pyramid-temple of the Magician crowning a majestic pyramid 80 ft. high and 240 by 180 ft. at the base; the Nunnery quadrangle composed of four large rectangular buildings enclosing a court, all on a terrace 300 ft. square and 15 ft. above the level of the plain, and all divided into numerous small rooms probably occupied by the priesthood; the Governor's palace, an imposing structure set upon a triple terrace, and said to be the most important single unit of its kind in America; the House of the Turtles, a smaller structure distinguished by a frieze of sculptured turtles on the moulding; and the House of the Pigeons, a quadrangle like the Nunnery quadrangle, of which one building carries a peculiar roof-comb of colossal size perforated by hundreds of openings which make it appear like a great dovecot, and which may have been occupied by statues like the roof-combs of Palenque. Besides these a number of smaller or less important ruins or groups of ruins dot the locality and help to create a scene of ancient power, prosperity and culture, probably unsurpassed in Yucatan and certainly rivaled only by Mayapan and Chichen-Itza.

(W. E. E.)

UZ, JOHANN PETER (1720–1796), German poet, was born at Ansbach on Oct. 3, 1720. He studied law, 1739–43, at the university of Halle, where he associated with the poets Johann Ludwig Gleim (*q.v.*), and Johann Nikolaus Götz (*q.v.*), and in conjunction with the latter translated the odes of Anacreon (1746). In 1748 Uz was appointed unpaid secretary to the *Justizcollegium*, an office he held for 12 years; in 1763 he became assessor to the imperial court of justice at Nuremberg, in 1790 was made a judge and, on the annexation of Ansbach to Prussia (Dec. 2, 1791), entered the Prussian judicial service, and died shortly after his appointment as *Landrichter*, at Ansbach on May 12, 1796. Uz wrote a number of graceful lyrics in Gleim's style, and some patriotic odes; he is the typical representative of the rococo period in German poetry. In 1749 the first collection of his *Lyrische Gedichte* was anonymously published, followed by *Der Sieg des Liebesgottes*, in alexandrines (1753), an imitation of Pope's *Rape of the Lock.*

UZ, a land, the scene of the story of the book of Job. Its precise location is uncertain, but the name in the Old Testament appears to be associated with three districts.

(1) *Northern Mesopotamia,* a district to which Uz, son of Aram, is commonly referred (Gen. x, 23).

(2) *Damascus* and the country lying to the south of it. Josephus (Antiq i, 6, 4) commenting on Gen x, 23, remarks that Uz founded Trachonitis and Damascus.

(3) *Edom.* In Gen. xxxvi, 28, Uz appears in the genealogy of Seir in the land of Edom, and in Lam. iv, 21, Uz stands as a parallel to Edom.

The suggestion has been made that if the name is so widespread, the explanation may be that it is tribal rather than territorial. The transcription of the name in the Greek version suggests the Arabic *Audh* a well-known deity, and might well be a tribal designation. Lam. iv, 21 appears to be the sole passage, which gives a clear indication of locality, and it is emphatic for Edom. *See* S. R. Driver and G Buchanan Gray, *The Book of Job* (1921), p. xxvii *seq*

(E. Ro.)

UZBEK or **UZBEG REPUBLIC,** one of the constituent republics of the U.S.S.R. in central Asia, created in 1924. Area 66,409 sq.mi. Pop. (1939) 6,282,450 (urban, 1,445,064; rural 4,837,386). Afghanistan lies to the south, the Turkmen S.S.R. to the west, Kazakstan to the north, and the Kirghiz S.S.R. and the Tajik S.S.R. to the east. It includes the oasis of Khwarezm, Khorezm or Khiva, Samarkand, and most of the former khanate of Bokhara, with the Ferghana valley. Tajikistan, as an A.S.S.R., and the Gorno-Badakhshan Autonomous area were until 1929 included in the Uzbek S.S.R.

Physical Characteristics.—The region is an ancient centre of oasis cultivation dependent on irrigation from glacier fed streams which are fullest at the time of the melting snows and are thus peculiarly favourable to agriculture. Its life depends on the Syr Darya, Amu Darya and Zarafshan rivers, on the spongy loess soil, and on the clear sunshine and heat of summer which combine to give rich harvests of grain and fruit to the cultivator The climate is continental, with little rain or cloud, and with intense bright sunshine in the six summer months. Extremes of temperature range between −13° F. and 117.5° F. or more, the contrast being greatest in the plains and least in the hill regions The severe winter prevents the growth of perennials, but annuals flourish in the summer heat Rainfall is always inadequate, but varies greatly from year to year.

The Zarafshan feeds the oases of Samarkand and Bokhara, the former getting the first and freshest supplies. It rises in a glacier in the Alai mountains of the Tadzhik A.S.S.R. and flows through a longitudinal valley with the Turkistan range to the north and the Hissar range to the south, its total length being 400 mi. and its average gradient 21 feet per mile Formerly it reached the Amu Darya, probably near Charjui, but now 12 mi. of sand, the Sundukli desert which connects the Kyzyl Kum from the north, and the Transcaspian Kara Kum from the south, intervene, and the river is lost in the creeping wind-blown sands which are slowly advancing on the little town of Kara Kul, the last settlement dependent on the "gold-strewer," as the Zarafshan is called.

The Kara Darya and the Naryn in the northeast unite near Namangan to form the Syr Darya and upon them depends the Ferghana valley with Andizhan, Marghelan, Ferghana, Khokand and Leninabad (Khojent) in the Tadzhik S.S.R. Tashkent lies to the north on the Chirchik tributary of the Syr Darya. A short portion of the Amu Darya forms the southern boundary of Uzbekistan and receives the right bank Surkhan tributary; the river then flows northwest through the Turkmen S.S.R. until it re-enters Uzbekistan and feeds the oasis of Khiva (*q.v.*), now suffering from difficulties caused by the increasing desiccation of the region and from the perpetual eastward shift of the river on its course to the Aral sea. Formerly the river entered the Caspian by the Sary-kamysh depression and the oasis was then much

more prosperous. Desert everywhere encroaches on the oases, in the northeast the famine steppe or Bak-pak-dala, with its salty dark gray clay soils, approaches close to Leninabad The Kara Darya and Naryn bring down vast quantities of sand which is deposited near their banks and especially on the banks of the Syr Darya, in the region where it cuts its way through the Leninabad-Ajar ridge

Under the influence of the southwesterly winds this vast expanse of sand everywhere steadily encroaches on cultivated lands In the northwest the Kyzyl Kum is advancing toward the Kamimikh district, and the oasis of Khiva lies between the Kyzyl Kum and the Kara Kum deserts Even in the fertile Ferghana valley there are stretches of rubble and stony, as well as of sandy, desert. The whole area is undergoing geological change; rivers have changed their courses and lakes their outlines, while in some cases they have dried up altogether. Traces of dried-up lakes and of river beds which were the main arteries of prosperous regions within the period of written history, are evident. Bokhara and Khiva owe part of their decay to this gradual desiccation Earthquakes occur, more especially on the line from Leninabad to Vyernyi (Alma-Ata) in the Kazakstan A S S R. In some regions, especially in the Urta Chul district between the western slopes of the Hissar range and the Amu Darya, there is stony steppe land, and steppe surrounds some of the oases and thus lessens the advance of sand. The juniper is common on the hill regions, and poplars and willows grow by the streams. The Russian government established a plant testing station to select shrubs to plant by the railway and thus prevent it becoming sand-covered, and at Marghelan there is a government forest station from which poplars and other young trees are distributed to cultivators, the quick growth of the poplar making it specially suitable for planting round orchards and fields. The former prairie fauna of the steppe regions is giving way to the drought-resisting plants of the semi-desert steppe, among these the *saxaul* scrub is particularly useful in a region deficient in fuel.

Agriculture.—During the civil wars and disorders following the 1917 revolution, the irrigation canals, which need constant cleaning and repairing, were neglected, and the sown area much diminished. This period was followed by a complete disorganization of the former system of water distribution, a disaster where every drop of water is precious. Only in 1925 was order restored and a new system introduced, based largely on the confiscation of water rights from former wealthy owners, and the redistribution under government control of water and of land from the large estates In a region where life was based on tribal and traditional systems, with recognition of the chieftain as owner and controller, this change, following on the disorders of civil war, made life difficult, especially as most of the inhabitants were illiterate and therefore found new laws particularly difficult to understand However, the age-long skill of the cultivators, primitive though their methods may be, and the great fertility of the region, resulted in the revival of agriculture.

The Russian government attaches particular importance to cotton cultivation for the supply of raw material to the cotton factories of the Moscow region. Efforts were therefore made to discourage the growing of rice, which demands a great deal of water; only on the left bank of the Chirchik in the Tashkent area can rice be cultivated without loss of water to other crops. Cotton from Uzbekistan, and especially from the Ferghana and Andizhan district, ordinarily supplies a large percentage of the requirements of the Russian cotton mills. The number of small cotton cleaning workshops has been reduced In 1926–27 a large cotton factory was built with 40,000 spindles. This was the first textile factory in central Asia. In 1926 a cement factory was opened at Khilkov.

The impact of industrialism on this region of immemorial tradition is already felt, especially among the women, some of whom have abandoned the veil and have formed co-operative clubs, especially in Tashkent and Samarkand. Products of the region include wheat, alfalfa, maize, sorghum, barley, melons, cucumbers, fruits, vines, oilseeds, millet and opium poppy The almond is common in the Ferghana valley. In the small areas not dependent on irrigation, wheat and barley are the chief crops In 1925 a government grant was made for the introduction of more modern agricultural implements, especially for cotton cultivation, which had developed by 1939 into a large-scale industry. Raising of sheep, goats, working cattle, horses, camels, asses, mules and pigs forms an important item among the nomad and semi-nomad tribes. Cattle and sheep breeding continues to be developed successfully, and the lamb fleece (Astrakhan) before World War II reached the world market in great quantities. Silkworm breeding is also an old and important occupation.

The republic has some mineral wealth, little developed as yet Naphtha near Ferghana gives an annual output of about 28,000 tons and coal, formerly exploited by peasants in a primitive way, but now under government control, yielded 101,000 tons from the mountains near the town of Andizhan. This development is due to the efforts of the soviet government to encourage local supply so as to leave the Donetz coal for the factories in European U S S R. Ozokerite is worked in Ferghana. Radioactive ores have been found at Tyuya Muyun in the Ferghana valley and are being exploited. Iron, silver, lead and copper are mined by the peasants for local use, but have little economic importance. The budget of the republic for 1940 was fixed at 1,476,300,000 roubles ($92,239,224 U S), for 1941 at 1,604,000,000 roubles

Industry and Communications.—Peasant industries everywhere supply local needs and supplement income. They include the making of clothing and of felt for the tents of the herdsmen, of leathern bottles and shoes, paper, woollen and silk goods (including carpets and shawls), and metal goods Dried fruits are an important export. Brick-making is unnecessary, for the loess, owing to its lime content, hardens, and loess mud huts are common

Many types of life are found within the republic. There still exist some purely nomadic herdsmen seeking different pastures according to opportunity, but their numbers are rapidly diminishing; others are semi-nomads with fixed summer and winter quarters. In the foothills there is some mixed farming with cattle raising and grain cultivation dependent on rain, while in the oases there is intensive grain and fruit cultivation under irrigation.

City life, with ancient trading bazaars and more recent beginnings of factory industry, is well developed Tashkent has a population of 585,005 (1939), Samarkand of 134,346 (1939). Khiva is much reduced and has 21,595 inhabitants. For an account of the ancient importance and present conditions of these famous cities *see* the separate articles on them. Other large towns, with their populations in 1939, are Kokand 84,665, Andizhan 83,691, Namangan 77,351 and Bokhara 50,382. Marghelan is under 50,000. It should be noted that all, with the exception of Khiva, are on the railway, a vital factor in their revival. The two main lines are the Chkalov-Tashkent and the line from the Caspian which meet at Tashkent. A branch goes along the Ferghana valley with a north and south loop from Khokand, and a branch from Bokhara goes south to Termez on the Amu Darya, with a loop toward Samarkand. Air communication is an important development since the revolution, and Tashkent, Samarkand, Termez and Stalinabad (in the Tadzhik S S.R) are linked by regular air services. There is no railway to Stalinabad and the road is difficult, so that the value of this air link which brings Stalinabad into touch with Tashkent and the railway by a six hours' flight cannot be overestimated. In this region of sharp contrasts, the camel caravan still crosses the desert and depends on wells which yield somewhat salty water, or on the rare freshwater springs

The Population diminished markedly during the civil war. The most densely peopled regions are the Andizhan and Ferghana districts and the Tashkent and Khiva oases. The total population of the latter oasis is little more than that of Tashkent city.

Uzbegs form about 76%, and other nationalities include Tadzhiks, Russians, Ukrainians, Kazaks, Kirghiz, and Jews. The latter are possibly descendants of Jewish prisoners brought here by Assyrian and Babylonian kings. They speak Iranian, but retain their ancient customs and are known as Bukhara Jews, because of the numbers in that city. The name Uzbeg dates back to the reign of Uzbeg Khan, a chief of the Golden Horde, who

died in 1340 and who introduced Islamism among his subjects; his coins have been found minted at all the towns of the Horde which struck money up to that date. Before the Mongol invasion, the Turks, of whom the Kazaks, Uzbegs, Turkmens and Osmanli are the four chief groups, occupied Dzungaria and the Mongolian desert. The great effect of the Mongol invasion was to push the Turks westward, and it was apparently Turkish tribes who adopted the name of Uzbeg from their Mongol ruler who introduced Islamism. The term Uzbeg is used by 14th and 15th century writers to indicate Mohammedan as opposed to Shamanistic Turks.

Klaproth gives four divisions of the Uzbegs, the Naiman, Kipchak, Kungrad and Mangut. The Kunkurats or Kungrads were driven from their original home near Lake Dalai Nor by the Mongols, and their name survives in the town of Kungrad on the Amu Darya delta. The Kipchaks form an important element in Khokand, while Tatar Uzbegs predominate in Khwarezm, where they founded an independent principality but allowed the Kurt and Turkmen cultivators to remain. In the 15th century Timur defeated the Uzbegs and sacked Samarkand, but the struggle between the Uzbegs and the Kalmucks in the early 16th century resulted in the former again occupying Samarkand

The Uzbeg (Jagatai Turkish) tongue, though closely related to Turki, seems to have had a separate origin and development Various indications connect it with the old Uighur dialect found in the *Kudatku Bilik* (AD 1070); an Uzbeg tribe in the Andijan district is called Uighur. At the present time, mainly as a result of the long illiteracy of the general population, there are numerous Uzbeg dialects, the four chief being those of Bokhara-Samarkand, Ferghana, Tashkent and Khiva, others being those of the mountain Uzbegs, of the Kashka Darya and Surkhan, the Afghan and the Kashgar districts Their variety reacts to-day by adding to the difficulties of education.

So much admixture of Mongol and Turk and original cultivators of the oases has gone to produce the Uzbeg, that the physical type is by no means uniform. The different proportions of Tadzhik, Sart, Persian and Afghan blood, as of Mongolian and Turkish, have led travellers to give most diverse accounts of the physical type of the Uzbegs. The Kuramas of the Chirchik (Tashkent district) seem to have much Kazak blood The name *Sart*, from old Turkish *to wander*, is found in the *Kudatku Bilik* in the sense of merchant as opposed to nomad and then indicated an Iranian people. In later times it denominated the original Iranian cultivators and ultimately has been used loosely of the peasant cultivators in the oases; it has no strict ethnological significance. The Persian speaking Tadzhiks were the aboriginal cultivators of the fertile parts of Turkistan and are tall and dark, with straight noses and much facial hair. They form a striking contrast to their Mongol and Turkish neighbours and are specially numerous in the towns For the history of the struggle between Turk and Mongol and Persian in this region and the varying fortunes of the khanates *see* H. Howorth, *The History of the Mongols* (1876).

History.—One of the earliest records of relations with Russia is the sending of envoys by the Uzbegs of Khiva to Tsar Feodor (1584–1598). In the previous reign an English merchant Jenkinson travelled to Bokhara, Ivan IV. (1533–1584) having granted an English company trading rights with Persia. Khiva was for long a slave market where in the 18th century as many as 10,000 Russian and Persian slaves sold in its markets by Kazaks, Turkmens and Kalmucks were working in the fields and on the irrigation canals. The Uzbegs became less hostile to the Russians after Peter the Great's campaign against their enemy, Persia, though a force which he sent against Khiva was annihilated.

In the 19th century Russian scientists and travellers visited the region, among whom was the famous Russian geographer Semenov, later called Semenov-Tian-Shansky. In 1847 Russian troops established a fort on the Sea of Aral at the mouth of the Syr Darya and in 1853 a steamer was launched in the hope, which was not fulfilled, owing to navigation difficulties, of establishing trading communication with Ferghana. In 1853 Ak Metchet (Perovsk) was captured and in 1864 Tashkent was occupied by the Russians, and two years later Khojent fell. In 1867 General Kaufmann was appointed governor of the newly created Turkistan province and in the next year Samarkand was captured. In 1870 the emir of Bukhara submitted to the Russians; since Bukhara is entirely dependent on Samarkand for its water supply a struggle would have been disastrous Khiva, however, secure in her desert fastnesses, still defied the Russian power. A Russian expedition under General Perovsky in 1869 was compelled to retreat by the difficult winter conditions in the Ust Urt plateau desert, with a loss of 3,000 men and most of the transport animals. In 1873 a triple attack from Tashkent, Chikishliar and Chkalov was organized and the city was captured. Khiva and Bukhara remained nominally independent vassal states of Russia until the 1917 revolution.

Soviet Government.—After that year they declared themselves independent republics and treaties with the Soviet government in 1920 and 1921 were signed in which their independence was recognized. Their form of government, however, was not socialist and soviet in type and civil war, complicated by the intense religious feeling of these Sunnite Mohammedan peoples, broke out. Finally in 1924, after prolonged civil fighting and disorder, the two republics disappeared and were merged in the Uzbeg S.S R. The creation of the new republic did not, however, imply a unity of feeling among its subjects. The Uzbegs themselves are divided into about 80 tribes with varying branches that bear at least 150 different names. The other races noted above complicate the problem and the difference of speech, custom and type of life will make amalgamation a slow and difficult process, and the difficulty is increased by the poor school provision.

The gulf between the materialist view of the Soviet government and the religious fanaticism of the Sunnite Mohammedans, especially of the town centres, will not be bridged quickly, though the first vigour of the Soviet attack on the Islamic faith has died down and many children in this region attend Mohammedan schools or *madrasas*. The encouragement of publication in the vernacular and of research in the institutes of Tashkent especially is producing a scientific and literary outlet for the more cultured Turkish peoples and the adoption of the Latin script in place of the more difficult Arabic makes for the increase of literacy, with an ultimate possibility of improving sanitary and social conditions.

UZÈS, a town of southern France standing on a height above the Alzon Pop (1936) 3,322. Uzès, the seat of an episcopal see from the 5th century to 1790, has a cathedral flanked by a 12th-century round tower of five stories. The Duché preserves a 14th-century donjon; the main building, flanked by a Gothic chapel, is Renaissance in style.

UŽICE, the capital of the Užice department of Serbia, Yugoslavia Pop (1931) 7,481. Užice (meaning "the narrow places") is built in a narrow, lonely glen, 1,385 ft. above sea level, on a stream spanned by two mediaeval stone bridges. Though poor, it has a well-built school, in the entrance to which is a Roman altar stone, and also a girls' school where weaving is taught. The surrounding heights produce excellent tobacco, and there are linen and cotton mills. Commerce is retarded by the bad roads.

In the 13th century Užice was the seat of St. Sava, the first archbishop and patron saint of Serbia.

UZZIAH, more correctly called Azariah, was seated on the throne of Judah in succession to his father Amaziah by popular choice at the age of sixteen (2 Kings xiv. 21 *sq.*, xv. 1–7). The records assign to him a reign of fifty-two years, covering roughly the first part of the 8th century B.C., but during part of this time his son Jotham, who succeeded him *c.* 740 B.C., acted as regent, because Uzziah had become a leper. He was for some years contemporary with Jeroboam II. of Israel, and both kingdoms flourished. Uzziah repaired the walls of Jerusalem and recovered and rebuilt the port of Elath on the Gulf of Akaba. The account of his military reorganization and successful campaigns in 2 Chronicles xxvi. is probably not without historic basis. The Chronicler explains his leprosy as a punishment for infringing priestly prerogatives. A certain Azriau of Yaudi appears in the inscriptions as leading a combination against Tiglath Pileser III. *c.* 739. It has been contended that the reference is to Azariah of Judah. Despite the striking coincidence of names, it seems probable that the leader was king of Y'di, a small independent kingdom mentioned in the Aramaic inscriptions found at Zenjirli. (W. L. W.)

THE history of this letter is identical with that of *U*, from which it was not differentiated till the 15th to 17th century. The letter passed out of Latin having a majuscule pointed form V and a minuscule rounded form u and doing duty for two sounds, the high rounded vowel (English *oo*) and the voiced labial spirant (English *v*). The consonantal sound was that most usually occurring when the letter was initial, in which position the majuscule form V would most generally be used. Thus the pointed form V became identified with the consonant, the rounded form with the vowel. A minuscule *v* and a majuscule *U* were then adapted as required. (B. F. C. A.)

VAAL, a river of South Africa, chief affluent of the Orange (*q.v.*). It rises at an elevation of over 5,000 ft. above the sea in the Drakenberg mountains, of the Transvaal, about 170 mi. in a direct line west of Delagoa bay. It flows in a general S.W. direction, with a markedly winding course, across the plateau of inner South Africa, joining the Orange in 29° 3′ S., 23° 36′ E. The river valley is 500 mi. long, the length of the river being 750 mi.

The first considerable tributary is the Klip (80 mi. long), which rises in the Drakenberg and flows N W., its junction with the Vaal being in 27° S, 29° 6′ E, 12 mi. S.W. of Standerton. From this point to the eastern frontier of the Cape, the Vaal forms the boundary between the Orange Free State and the Transvaal. The river is usually shallow and is fordable at many places, known as *drifts*. But after the heavy summer rains the stream attains a depth of 30 or more feet. At such times the banks, which are lined with willows and in places very steep, are inundated. As a rule little water is added to the Vaal by its tributaries. On the north the basin of the Vaal is contracted by the Witwatersrand and the Magaliesberg ranges, and its trubutaries are few

The Mooi rises in the Witwatersrand west of the Klip and, after running almost due S 75 mi., unites with the main stream about 90 mi. below Vereeniging. In its course through Griqualand West, the Vaal flows in a wide rocky channel, with banks 30 ft. high, through an alluvial plain rendered famous in 1867–70 by the discovery of diamonds in the bed of the river and along its banks. The diamonds are washed out by the water and found amid debris of all kinds, frequently embedded in immense boulders. The last affluent of the Vaal, the Riet river, rises in the Beyers Bergen S.E. of Reddersburg and flows N W. 200 mi. through Orange Free State, being joined, a mile or two within the Cape frontier, by the Modder river (175 mi.), which rises in the same district as the Riet but takes a more northerly course. The united Riet-Modder joins the Vaal 18 mi. above the Orange confluence.

The name Vaal is a partial translation by the Dutch settlers of the Hottentot name of the river—Kai Gariep, properly Garib (yellow water) which refers to the clayey colour of the stream. The Transvaal is so named because the first white immigrants reached the country from the south by crossing the Vaal.

VAALPENS (dusty-bellies), a little-known nomadic people of South Africa, who lived in small groups in the Zoutpansberg and Waterberg districts of the Transvaal, especially along the Magalakwane river. The Vaalpens were so called by the Boers from the dusty look of their bodies, due, it is said, to their habit of crawling along the ground when stalking game. But their true colour was black. In height the men averaged about 4 ft., *i.e.*, somewhat less than the shortest Bushmen. The Vaalpens lived entirely by hunting and trapping game, and dwelt in holes, caves or rock shelters. They wore capes of skins, and procured the few implements they needed in exchange for skins, ivory or ostrich feathers. Their speech was full of clicks.

VACARESCU, the name, according to tradition, of one of the oldest noble families in Walachia. The first member of historical importance was IANACHE (b. 1654), the grand treasurer of Walachia, who was killed with his master, Prince Brancovan in Constantinople, 1714. His grandson through his son Stephan, also called IANACHE (or "Enakitza the Ban," 1730–1796), started a line of Rumanian scholars and poets; he was the author of the first known Rumanian grammar in the vernacular, printed in 1787. While in exile in Nicopolis he wrote the contemporary history of the Turkish empire in two volumes (1740–99). He was also the first to attempt Rumanian versification. Greater as a poet was his son ALECU (Alexander), who died as a prisoner in Constantinople in 1798. In 1796 a collection of his poems appeared in Rumania. His brother Nikolaes (d. 1830) also wrote some poems, but they remained in ms. until 1860, when they were published.

By far the greatest member of the Vacarescu family in the male line was IANCU (1786–1863), the son of Alexander. An ardent patriot, he sided with the national movement in 1821, and assisted in establishing the Rumanian theatre, translating many books and plays from German and French into Rumanian, notably the *Britannicus* of Corneille, a literary event of no small importance at the time. He inaugurated modern Rumanian poetry. In 1830 appeared his first volume of verse He died in 1863 A niece of Alexander was the gifted writer ELENA VACARESCU (Hélène Vacaresco) (1866–1947), maid-of-honour to the queen of Rumania, and Rumanian delegate to the League of Nations, who inherited the talent of her family and enriched Rumanian literature with her *Bard of the Dimbovitza*, and other poems and novels in Rumanian and in French, including *Chants d'Aurore*, which was crowned by the French academy; *L'Âme Sereine*, and *Rumanian Ballods*, which obtained the Prix Jules Favre at the French academy. (M. G)

VACARIUS (1120–1200?), Italian civilian and canonist, the first known teacher of Roman law in England, was of the school of Bologna, though of a later generation than the hearers of Irnerius. He was taken to Canterbury, possibly by Thomas Becket, together with a supply of books upon the civil law, to act as counsel (*causidicus*) to Archbishop Theobald in his struggle, which ended successfully in 1146, to obtain the transfer of the legateship from the bishop of Winchester to himself. Vacarius is next heard of as lecturing at Oxford, in 1149, to "crowds of rich and poor," and as preparing, for the use of the latter, a compendium in nine books of the Digest and Code of Justinian, "sufficient," it was said, "if thoroughly mastered, to solve all legal questions commonly debated in the schools." It became a leading textbook in the nascent university, and its popular description as the *Liber pauperum* gave rise to the nickname *pauperistae* applied to Oxford students of law. Nearly complete mss of this work remained in existence, notably in the cathedral libraries at Worcester and Prague and in the town library at Bruges Fragments of it were also preserved in the Bodleian and in several college libraries at Oxford

The new learning was not destined to make its way without opposition. King Stephen silenced Vacarius and ordered the destruction of the books of civil and canon law which had been imported by Theobald The edict to thus effect seems, however, not to have been in force after the death of its royal author in 1154 ("eo magis virtus legis invaluit quo eam amplius nitebatur impietas infirmare," Joh. Sarisburiensis). Whether or not Vacarius ever resumed his Oxford lectures after their interruption by Stephen is not known. In any case he was soon called to practical work, as legal adviser and ecclesiastical judge in the northern province, by his old friend and colleague at Canterbury, Roger de Pont l'Évêque, after the promotion of the latter, in the year of Stephen's death, to the archbishopric of York. Thenceforth the name of "magister Vacarius" is of frequent occurrence in papal letters and the chronicles of the period, as acting in these capacities. He was rewarded with a prebend in the collegiate church of secular canons at Southwell, half of which he was allowed in 1191 to cede to his "nephew" Reginald. He is last heard

of in 1198, as commissioned, together with the prior of Thurgarton by Pope Innocent III to carry into execution in the north of England a letter with reference to the crusade It is doubtless to the second half of the life of Vacarius that the composition must be attributed of two works One of these, *Summa de assumpto homine*, is of a theological character, dealing with the humanity of Christ; the other, *Summa de matrimonio*, is a legal argument to the effect that the essential fact in marriage is neither, as Gratian maintains, the *copula*, nor, as Peter Lombard, consent by *verba de praesenti*, but mutual *traditio*

BIBLIOGRAPHY —Most of the original authorities are textually set out and annotated by Prof T E Holland in vol. II of the *Oxford Historical Society's Collectanea* (1890) Wenck, in his *Magister Vacarius* (1820), prints the prologue, and a table of contents, of the *Liber pauperum*, from a ms now lost. F. Maitland in the *Law Quarterly Review*, XII, pp. 133, 270 (1897), gives a full account of the Cambridge mss printing *in extenso* the *Summa de matrimonio*.

VACCINATION, strictly speaking, is the implanting of the living virus of cowpox in a person to protect him against smallpox The procedure was introduced to supersede "inoculation," the artificial implanting of smallpox virus, in order to protect against smallpox acquired in the natural way The inoculated smallpox commonly gave only a sparse general eruption of pocks, with a fatality rate much lower than that of the natural smallpox, which otherwise was a hazard to be expected by everyone in the 18th century.

Edward Jenner (*q v*) in his original publications of 1798–1800 did not use the term "vaccination" but spoke of "inoculation for the cow-pox." In devising a Latin term for this disease, previously without medical description, he called it "*Variolae* [plural noun meaning 'smallpocks'] *vaccinae*" (adjective meaning "of the cow," from Latin *vacca*, a cow). From this Latin of Jenner's the French in 1800 coined the term "vaccination," half in derision, for the implantation of cowpox. To the French and to those versed in Latin, "vaccination" would mean "en-cowing." "Vaccine," an adjective meaning "of the cow," then "of the cowpox," later became a noun meaning the material used for vaccination

Jennerian vaccination against smallpox was the first, and for nearly a century the only, successful immunizing procedure against any disease, other than by inoculation with, or exposure to, the real disease itself.

In 1881 Louis Pasteur demonstrated immunization against anthrax by the injection of a comparatively harmless attenuated culture of the bacillus causing that disease He then used the terms "vaccine" and "vaccination" for prophylactic inoculation in general as homage, he said, "to the merit and to the immense services rendered by one of the greatest of Englishmen, Jenner." Four years later Pasteur developed rabies vaccine His work led to wide extension of immunizing methods against many diseases with correspondingly widened meanings of the terms "vaccination" and "vaccine," applying them to the use not only of living but also of dead material.

The present article deals with vaccination in its original and stricter sense; that is, vaccination against smallpox. This is still approximately the most perfect method of immunization against any disease, judged by the security and duration of protection in proportion to its inconvenience.

Jenner, trusting too much to the stories of the country people in his neighbourhood, believed that the cowpox, and perhaps the smallpox, originated in an infection of the heels of horses. The evidence accumulated, however, that the natural occurrences of cowpox started from the hands of milkers afflicted with smallpox when the latter disease was widely prevalent. The infection was disseminated through dairy herds by other milkers on whose hands it took the changed form of cowpox. Strains of good cowpox virus were artificially started, chiefly in Germany, by transfer of smallpox virus to the cow, more readily through other animals, such as the monkey or the rabbit, first. Such strains propagated from smallpox virus were called variola vaccine.

Smallpox virus is not so easily transmitted to lower animals as is vaccine (cowpox) virus. The different establishments preparing vaccine virus have had the habit, when their particular strain showed signs of weakening, of reinforcing it with strains of virus from other establishments. Thus the strains can hardly be traced back to any one particular source. Jenner himself lost strain after strain, using new ones from time to time derived from natural cowpox found in dairy herds or their milkers. The from natural cowpox found in dairy herds or their milkers. The remarkable fact is that his descriptions and pictures of the day-to-day appearance of the vaccinated arm, and the descriptions and pictures of the most careful observers since his publication, have coincided exactly with the appearance of arms vaccinated with good strains of modern vaccine virus, particularly the rapid spread of the area of redness surrounding the vesicle after the seventh day in a previously unimmunized person This is different from the appearance after any other sort of inoculation, and such an inoculation has always given protection against smallpox anywhere in the world Even the obsolete inoculation with smallpox virus itself produced a different course of events as to the inoculated arm, besides later giving rise to an eruption of pustules over the other areas of the body

Originally the virus was carried from arm to arm, the vaccinated persons being told to return on the seventh day so that the contents of the clear vesicles at that time could be transferred to the arms of the next set to be vaccinated. Crusts of the dried vesicles, or vesicle contents dried on quills or threads or ivory points, were also used. Later, strains of vaccine virus were carried back to the cow for one or more passages in an attempt to make them stronger This was called "retrovaccination." By the early years of the 20th century nearly all vaccine virus was propagated on calves (carabao in the far east), suspended in glycerine solution and distributed in hermetically sealed capillary tubes Occasional passage through other species, such as the rabbit, appears to aid in maintaining the purity and the potency of the virus. In Spain rabbit-brain virus was used instead of calf virus, and many essays have been made to substitute growth in the chick embryo (fertilized egg) for growth on the bovine skin A theoretical objection to such procedures—not without some confirmation in experience—is that the virus should not be adapted to deep proliferation in the layers of body tissue; human vaccination is safest from disagreeable results when it is as superficial as possible Dried virus has also been used, and, though inconvenient and expensive to dilute unless many are to be vaccinated at one time, it has served a useful purpose where prolonged transportation to warm climates is necessary. The greatest advance in the prevention of smallpox in the 20th century was the cold storage of the vaccine virus (below freezing) up to the time of use.

Need.—Increased global travel, the presence of virulent strains of the disease in various parts of the world (*see* also SMALLPOX OR VARIOLA), its great contagiousness and the fact that no population is sufficiently vaccinated to be proof against a smallpox epidemic are sufficient reasons for keeping up vaccination in spite of the remarkable decline in smallpox cases. Vaccinations regularly carried out are preferable to emergency vaccination of a population at risk. All foreign travellers in both directions need the successful application of fully potent vaccine before undertaking the journey.

Efficacy and Time of Vaccination.—Jenner was misled into thinking that one successful vaccination gave lifelong protection. It is possible that the continual exposure to smallpox to which people were subject in his day tended to keep up the immunity initiated by cowpox Vaccination every five years is a safe general rule, but for nurses, physicians and hospital attendants constantly in danger of exposure, and for foreign travellers in similar danger, once a year is safer There is always the danger that the tube of vaccine used may not have been constantly refrigerated; this explains accounts of smallpox after recent vaccination. A case of smallpox within two years after a successful vaccination is extremely rare even though exposure is ample, and such a case of the disease is mild There are great differences between individuals in the firmness of holding on to immunity toward smallpox, just as there are toward other infections A not inconsiderable proportion of a population might be protected against smallpox for life by one vaccination, though they would lose their immunity to vaccinia (cowpox) more readily. Long after complete protection subsides, a former vaccination modifies the severity of an attack of smallpox.

There are great advantages in having the first vaccination performed during the early months of life. Infantile vaccination, if properly performed and cared for, is milder than a later first vaccination, usually giving rise to no inconvenience whatever; it makes the subsequent vaccinations, if decades are not allowed to pass without revaccination, much milder affairs Protection is gained not only against smallpox but also against accidental vaccination from the arm of a playmate or associate, and the scar of such an early vaccination becomes much less noticeable than if the first vaccination is performed later. The first spring of a child's life is probably the most favourable time for vaccination

Disadvantages.—The former and cruder methods of preparing the vaccine and performing the inoculations, together with the stern measures with which compulsory vaccination was enforced, naturally aroused opposition. One cannot expect something for nothing, and the remarkable protection which vaccination bestows is bound to entail a slight risk, at least of inconvenience. With proper vaccine, procedure and care, the risk is negligible compared to the advantage to the community and the individual. Clean technique, with a small adequate inoculation in only the most superficial layers of the skin, on an arm which is kept dry and cool, covered by no dressing except the loose clean sleeve of the child's garment, ensures for the great majority of vaccinations a perfectly satisfactory course. No practical cleansing can remove all the bacteria from the skin, however, and occasionally, especially in leg vaccinations, the vesicle may become purulent on this account and the drying process be delayed or even require attention Eruptions soon after the maximum reaction are seen at times but disappear rapidly without treatment. Tetanus following vaccination formerly occurred once in a while, but later was entirely prevented by proper technique and particularly by allowing the vesicle of vaccination to dry naturally without dressing, shield or bandage Authentic cases of demyelination encephalomyelitis have been reported after vaccinations as after other inoculations or infections, but never where the above precautions were followed and the first vaccination was performed in early infancy.

Course.—In a first vaccination on a child with good vaccine and good technique, nothing is usually seen until the third day, when a papule (pimple) appears at the site The central part of this papule soon develops into a vesicle (that is, contains fluid) and is surrounded by a narrow red zone It is the behaviour of this red zone which constitutes the characteristic and important detail in the course of the reaction. While the vesicle is enlarging at the rate of about a millimetre a day in diameter, the red zone remains of moderate size until about the 7th day, when it rapidly begins to enlarge, reaching its greatest diameter between the 8th and the 14th day after vaccination, then disappears as rapidly The vesicle meanwhile continues to enlarge slowly, but before the height of the reaction is reached starts drying from the centre, forming a dark crust (scab) which drops off about three weeks after vaccination, leaving a clean pink scar which becomes white in about a year. A day or two of fever is often observed without particular relation to the course of the reaction. Care should be taken (as in bathing) to keep moisture away from the vesicle and crust until the latter comes off. The reaction above described is called primary vaccinia.

In more than half the revaccinations performed with fully potent vaccine on a group of people who had their previous vaccinations 10 to 40 years before, the appearance of the arm on successive days will be somewhat similar to that described in the preceding paragraph except that the course will be accelerated to give the greatest diameter of the red zone between 72 hours and seven days after vaccination; usually the spread and subsidence of the redness is more gradual than in vaccinia. Such a reaction is called vaccinoid and indicates partial protection against smallpox.

In what may be called the early reaction of vaccination the broadest redness occurs within 72 hours after vaccination and there may or may not be a vesicle. One is not justified in saying that this indicates previous complete immunity against smallpox unless full potency of the vaccine can be assured; the history of the cold storage and the results with that batch of vaccine are seldom sufficiently known. Practically an exact counterpart of the early reaction or even one simulating the vaccinoid reaction may be given on a person with little or no immunity when vaccine of less than full potency is used.

If observation is thorough, every adequately performed vaccination with potent vaccine will be found to give a reaction which can be classified in one of the above categories: vaccinia, vaccinoid or early reaction.

VACCINE THERAPY. Vaccine therapy results in the induction of a state of active immunity in an individual, either for the purpose of preventing the development of a specific infectious disease, or in some cases as a means of treatment of an already established infection The actively immune state is induced in the person or animal being immunized by the introduction into the body of a vaccine composed of suspensions of living or dead microorganisms of a specific kind, or of some of their metabolic products. These substances in the vaccine stimulate the body cells to modify normal globulin molecules so that they acquire a very high degree of specificity against the disease-producing micro-organisms or their products from which the vaccine was originally prepared The altered globulin molecules or antibodies, as they are called, are the immune substances in the blood, and distributed throughout the body, which combat the subsequent invasion of the microorganisms, or help control the multiplication and spread of infectious agents already established in the body.

The principle of using a less virulent, or attenuated, microorganism to induce active immunity for protection against a particular disease originated in the orient. In ancient times the crusts from lesions of very mild cases of smallpox, containing the weaker virus, were applied in one of several ways to the skin or nasal mucous membranes of persons who wished protection against a severe case of smallpox The Turks accomplished the same purpose by scratching the crusts from lesions of mild smallpox into the arm of the person to be immunized This procedure, known as variolation, was introduced into England by Lady Mary Wortley Montagu (1689–1762). The practice was not free from risk, and some persons developed a virulent generalized case of smallpox and died.

To Edward Jenner, a British country physician, goes the credit for his discovery, reported in 1798, that infectious material (vaccinia virus) from lesions of cowpox (vaccinia) could be inoculated artificially into the skin of man, and thus induce immunity against smallpox Hence the terms vaccination and vaccine were originally used only in relation to immunization against smallpox with vaccinia virus. Louis Pasteur and others later applied the same principles to the prophylaxis of other virus, bacterial and rickettsial infections. Consequently, the term vaccine came to be used in a broader sense, including suspensions of living attenuated or dead infectious agents, emulsions of their cellular constituents and solutions of their altered metabolic products (toxoids). Sir Almroth Wright extended the principles of active immunization to include not only the prevention but also the treatment of infectious diseases. Regardless of whether the desired result of active immunization is the prophylaxis or therapy of a particular infectious disease, the procedures of vaccine preparation and immunization are essentially the same The person to be immunized is usually inoculated with the vaccine by intradermal, subcutaneous or intramuscular injections at regular, specified intervals. The degree of immunity resulting from the administration of a vaccine is quite variable; it depends on several factors including the antigenic potency of the preparation, the dosages given, the time interval

between injections and the degree of ability of the person to produce anibodies when properly stimulated

Early successes in the development and use of vaccines in the prevention of smallpox, anthrax and rabies encouraged attempts to develop actively immunizing agents for many other diseases. Effective vaccines were also developed for active immunization against typhoid and paratyphoid fevers, cholera, plague, tuberculosis, undulant fever, whooping cough, tularaemia, chronic staphylococcal and streptococcal infections, diphtheria, tetanus, influenza, yellow fever, Japanese B encephalitis, Russian tick-borne encephalitis, St. Louis encephalitis, equine encephalomyelitis, Rocky mountain spotted fever, typhus and against several important diseases of animals.

A true evaluation of the efficacy of vaccine prophylaxis is exceedingly difficult to obtain for many diseases It may be readily understood that it is often impossible to arrange experiments involving sufficient numbers of individuals in the inoculated and uninoculated or "control" groups to assure statistically significant analyses of the results This is particularly difficult in diseases which have relatively brief incubation periods, or in which exposure to the disease is irregular and unpredictable, such as those diseases which do not ordinarily occur in epidemic form in the population. At mid-20th century, adequate statistical data concerning the effectiveness in humans of some of the virus vaccines was still lacking, although protection tests in experimentally infected animals indicated their probable value. The difficulty in correctly evaluating the effectiveness of vaccines is even greater when they are employed in the treatment of individuals already suffering from an established infection. Such cases must be judged separately; other therapeutic measures and the possibility of coincidence must be seriously considered when attempting to form a correct estimate of the value of vaccine therapy. In many diseases, such as typhoid and paratyphoid fevers, there is overwhelming evidence for the high degree of protection established by vaccination; in other diseases there is evidence of definite value from vaccination, even though it may not always be protective, as in whooping cough; in still others, the results of vaccination are equivocal. However, there is no question concerning the importance of specific active immunization.

Types of Vaccines.—There are two main types of vaccines—stock or heterogenous, and autogenous. Stock vaccines are prepared from microorganisms previously isolated from persons having a particular infectious disease After identification of the causative agents, they are cultivated or stored in the laboratory. Since bacteria of the same species may exhibit biological variations and minor differences in antigenic structure, stock vaccines may be composed of several different strains of the same species, thereby rendering the vaccine polyvalent. Treatment with such polyvalent stock vaccines is of distinct value particularly in certain chronic infections. Obviously stock vaccines must of necessity be used only in an attempt to immunize the normal individual prior to exposure to infection by the corresponding infectious agent.

Autogenous vaccines are prepared from the actual microorganism isolated from the particular patient being treated. Such preparations are definitely superior to even polyvalent stock vaccines in the treatment of chronic infections, such as sinusitis or pyoderma, since the resulting antibodies developed are entirely specific for the particular agent causing the disease.

For the prevention of tetanus and diphtheria, diseases in which the chief symptoms and pathology result primarily from the effects of the bacterial toxins in the body, the modified toxins, or toxoids as they are called, comprise the vaccine, and stimulate the production of immunity which is antitoxic rather than antibacterial.

Preparation of Vaccines.—Bacterial vaccines, whether stock or autogenous, are prepared in a manner somewhat as follows: the selected microorganism is grown, usually on a solid culture medium under conditions which are optimum for maximum growth. The resulting bacteria are suspended in a sterile physiological solution of sodium chloride, washed by centrifugation and resuspended in more of the sterile saline solution. If the vaccine is to be composed of intact bacterial cells, the microorganisms are usually killed, either by heating in a water bath at 60° C. for one hour or by the addition of some chemical The number of bacteria per unit volume of suspension is determined by any of several ways. by density determinations, by chemical analyses or by direct or proportional microscopic counts The bacterial suspension is then adjusted to the desired standard by either dilution or concentration, as the need may be, and cultured to ensure its sterility. The standardized sterile vaccine is stored in sterile glass vials or ampuls and is ready for use.

If the vaccine is to be composed of fragments of bacterial protoplasm, rather than of the intact bacteria themselves, the bacteria are killed by disrupting the cells, after their concentration is standardized, either by repeated rapid freezing and thawing of the suspension, by grinding in a ball mill, by ultra-violet irradiation or by ultrasonic vibrations The resultant mixture of bacterial antigens is tested for sterility to ensure its noninfectivity, and a preservative, such as phenol, is added in proper concentratidn.

Virus and rickettsial vaccines are prepared in a manner somewhat similar to the above, except that these microorganisms must be cultivated in the presence of living animal cells. Ernest Goodpasture's development in 1931 of the embyronated hen's egg as a culture medium for many viruses and rickettsiae provided the opportunity for producing vaccines of many of these infectious agents.

VACCINIUM, a genus of shrubs of the heath family (Ericaceae, *q.v.*), comprising about 130 species found widely throughout the northern hemisphere, and extending to Madagascar and the Andes

They are erect or creeping shrubs, with deciduous or evergreen leaves The small flowers bear much resemblance to those of the true heaths (*Erica*), from which they differ in having the ovary inferior. The fleshy, often delicious, berries are usually edible. Four species occur in Great Britain: *V. myrtillus*, the bilberry, blaeberry or whortleberry; *V. uliginosum*, the bog bilberry; *V. vitis-idaea*, the red whortleberry or cowberry; and *V. oxycoccos*, the cranberry (*q.v.*), all of which are found widely distributed throughout large areas in Europe, Asia and North America, being especially abundant in cool northern and mountainous regions.

In North America some 40 species occur, more abundant in the northern and mountainous parts of the continent. In the eastern states and adjacent Canada several species, commonly known as blueberry (*q.v.*), are prized for their fruits. In northern Canada the red whortleberry, commonly called mountain cranberry, is gathered for cooking purposes. *V. macrocarpon*, the American cranberry, is extensively cultivated Several species occur in the Rocky Mountain region and about ten are found in the Pacific states, the latter including *V. occidentale*, the western blueberry; *V. parvifolium*, the red bilberry; and *V. ovatum*, the California blueberry.

VACUUM, empty space, specifically, an enclosed space devoid of matter. Physically, the condition of complete absence of matter is never realized; even the most nearly perfect vacuum contains gas or vapour in a state of great rarefaction—how great may be realized by considering that the lowest practicably attainable pressure in a tight vessel is of the order of 10^{-7} mm. of mer-

cury, whereas atmospheric pressure is about 8.75×10^5 mm.—the height of the mercury column in a barometer. The ratio of these pressures is about 1.3×10^{-10}; in round numbers, therefore, the pressure in the vessel, as well as the number of molecules of gas in it, has been reduced by a factor of 10,000,000,000. In each cubic centimetre of gas at normal atmospheric pressure there are 2.7×10^{19} molecules. Reducing the pressure to the practicable limit therefore reduces the number of molecules by a factor of, say, 10^{10}, leaving behind 2.7×10^9 molecules, or roughly 3,000,000,000, in each cubic centimetre of space within the vessel. Whereas at atmospheric pressure the mean free path (average distance covered between collisions) of a molecule in air is about 9.5×10^{-6} cm., this becomes 14 m. at the low pressure mentioned.

During the years between the World Wars I and II, and particularly during the prodigious scientific and technological efforts in the United States and Great Britain brought forth by the exigencies of World War II, great strides were made in the application of high-vacuum technology to many problems and situations, both in the laboratory and the factory, in fields of great diversity in pure and applied science.

It is general knowledge that Thomas A. Edison's incandescent electric lamp required that its glass envelope or bulb be "pumped out" to prevent its carbon filament from uniting with the oxygen of the air and chemically burning out. The commercial needs of rapidly exhausting the air from light bulbs resulted in improvements in methods of pumping. The "Edison effect"—forerunner of the Fleming valve, the Deforest audion, and the multitude of modern electronic tubes—was discovered because it had become possible by 1883 to pump the air out of a lamp bulb to the point where a current through the residual gas could be detected. The rapid growth of the radio industry, accompanying the development of broadcasting methods and of means for broadcast reception, which occurred in the decade beginning about 1920, could not have occurred without the concomitant development of techniques for exhausting the radio valves, or vacuum tubes, to the requisite high vacuum by methods that were technically and economically feasible

Metallurgical processes by which such rare metals as tantalum and tungsten are produced in pure state from their ores depend for their success on high-vacuum furnaces in which the vacuum can be rapidly produced and readily maintained while the metallic bars, at white heat, are giving off great quantities of gas. Practically all optical instruments used in World War II were greatly improved in their ability to transmit light by having the optical surfaces of their lenses and prisms coated or "bloomed" with a hard, transparent mineral layer a few molecules thick, to reduce the reflection and therefore loss of light at these surfaces. The coating process is carried on in a high vacuum, and its development to commercial practicability comprises many highly ingenious procedures. In the optical field also, the best first-surface mirrors are produced by a vacuum distillation process, in which the metal is vaporized by electric heat and caused to condense on the glass surface from which light is to be reflected. The mirrors of practically all astronomical reflecting telescopes are now prepared by evaporation and condensation of metal—usually aluminum—in a high vacuum.

The production of vitamin A from fish-liver oil, by fractional distillation in a high-vacuum still, is now a highly successful commercial process; but this is only a single example of a well-developed technology in the fields of nutrition and pharmacology yielding useful and valuable and sometimes unexpected returns. High-vacuum technology plays an essential role in the production, in commercial quantities, of penicillin, and in the rapid dehydration of blood plasma and serums

In the basic science laboratories, particularly those of physicists, the availability of apparatus for the rapid production of high vacuum has profoundly influenced the success of many researches. It has, in fact, been the *sine qua non* of some of the most fundamental experiments in electronics, nuclear physics and X-rays Without high vacuum there would be neither radio broadcasting nor radio reception; and without it, television could not have been developed. For it is only in high vacuum that the electrons may be given off and controlled to make tubes and circuits possible in which a weak signal may be amplified ten-millionfold and more; and it is in high vacuum that light may cause useful emission of electrons from a photosensitive surface which constitutes the heart of the television transmitter. The cathode-ray oscillograph, one form of which is essential to the production of a visible image in a television receiver, likewise depends on high vacuum. The cathode-ray oscillograph may be said to have saved England, for it is one of the essential components of radar. The cyclotron, the betatron, the electron microscope, the mass spectrograph—all are useful, practicable instruments because of high vacuum. The separation of U-235, the fissionable atom of uranium, from its isotopes of atomic weights 234 and 238, was accomplished in high vacuum, in a magnetic field, by applying the principle of the mass spectrograph.

These examples from industry and the research laboratory have been cited to show the importance of vacuum, and particularly of modern high-vacuum technology. The requirements of the innumerable situations in which high vacuum is an essential factor have given rise to a modern technology that may be designated "high-vacuum engineering" This comprises a knowledge of the means for producing high vacuum, namely, the several kinds of vacuum pumps, formerly called air pumps; the means for measuring vacuum—the several kinds of manometers or vacuum gauges; and the unusual methods and artifices that must be employed in order that a vacuum system—consisting of the pump or pumps, the vessels or containers being exhausted, the measuring and controlling devices and the tube-lines connecting all together properly—may function most effectively These several aspects of production and measurement of high vacuum and the management and control of vacuum systems will be discussed in this article.

Rotary Oil-Sealed Pumps.—About 1920 the reciprocating-piston vacuum pump was displaced by the rotary mechanical types Some ten years earlier the Gaede *Kapselpumpe* had appeared It was characterized by a cylindrical rotating member, or rotor, eccentrically mounted within a cylindrical housing, or stator, of somewhat larger diameter (fig. 1). The rotor A contained two diametrically opposite slides, S and S′, bearing against the inner surface of the stator B under spring pressure and centrifugal action Air in the space V_0 ahead of the slide S′ is swept out through an exhaust port, as the volume of the space decreases; whereas, behind the slide S the volume increases, causing air to enter through an intake port from the vessel being exhausted. Air in the space V between the two slides, at the pressure of that in the vessel being exhausted, is compressed, as soon as slide S′ has passed the exhaust port and V has become V_2, to atmospheric pressure, and is expelled through the valve E to atmosphere. Small clearance and an oil film at C keep the compressed gas in V_2 from entering V_1. Many rotary pumps of various specific designs but employing the same principle have appeared and are in common use in shops and laboratories. The Gaede rotary *Kapselpumpe* was designed to serve as a primary or forepump (Ger.: *Vorpumpe*) in series with the Gaede rotary mercury pump with which high vacuum could be slowly produced. More recent designs of rotary pumps have been used in large numbers as forepumps with the mercury vapour diffusion or condensation pumps, and with the oil-vapour pumps of this type.

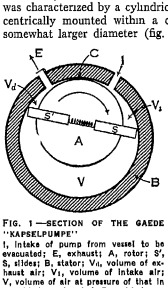

FIG. 1—SECTION OF THE GAEDE "KAPSELPUMPE"
I, intake of pump from vessel to be evacuated; E, exhaust; A, rotor; S′, S, slides; B, stator; V_0, volume of exhaust air; V_1, volume of intake air; V, volume of air at pressure of that in vessel being exhausted; C, seal between stator and rotor

The type of rotary pump, which was responsible for displacing the reciprocating air pump from laboratories generally, is a series known as "Hyvac"—with displacements ranging from about 170 cc. to 17,000 cc. per second. These represent the first rotary,

oil-sealed pumps capable of producing a vacuum—with exclusion of vapour from the system—of better than 0·001 mm of mercury In principle this type differs from the pump of fig 2 in having its rotor eccentrically mounted on a shaft, and in having a single vane in the stator to separate the high-pressure from the low-pressure side.

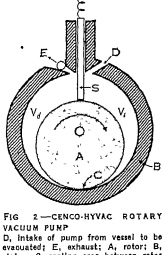

FIG 2.—CENCO-HYVAC ROTARY VACUUM PUMP
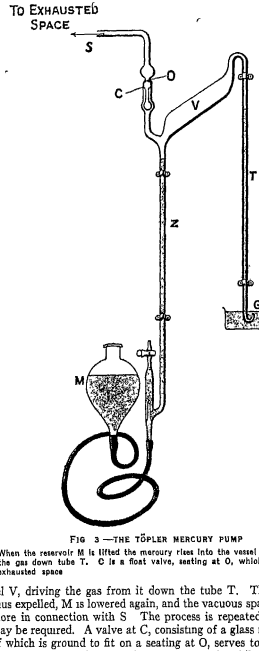
D, intake of pump from vessel to be evacuated; E, exhaust; A_1 rotor; B, stator; C, sealing area between rotor and stator; S, slide; V_d, intake volume; V_d, exhaust volume

In fig 2 Rotor A is eccentrically mounted on a shaft concentric with the cylindrical cavity of stator B At C the surface of the rotor is ground, for a short distance, on a radius almost equal to that of the stator cavity, to provide sealing contact over a finite area rather than along a cylindrical element, or line The slide S is maintained in contact with the rotor by spring pressure. The intake is at D, the exhaust port at E; the latter is provided with a ball valve With rotation as indicated, the space V_i increases and V_d decreases at each cycle from the instant of passage of the sealing area C beyond the slide S. In its practical embodiment, this pump may consist of two pumping units in series. They are arranged side by side, separated by a common wall, ground plane-parallel, through which a hole is drilled that constitutes both the exhaust port of the high-vacuum unit and the intake port of the forepump unit. While the space V_d in the former is decreasing, it is expelling the air into the space V_i of the latter. Thus the air in the space V_d of the high-vacuum unit is not compressed appreciably. As a result, leakage into the high-vacuum side is minimized. In illustration of the effectiveness of such an arrangement, a single-stage pump of this type produces a vacuum of about 0·05 mm, whereas the two-stage pump produces about 0.0005 mm., two orders of magnitude better.

Pumps Utilizing Liquid Mercury.—In the second half of the 19th century various types of mercury pump were introduced, which were used in all the early experiments on the discharge of electricity through gases at low pressure. The principle of all these pumps is to connect the receiver with a Torricellian vacuum created by the pump, the equalization of pressure will then bring part of the air in the receiver into the Torricellian space. The receiver which is being exhausted is then cut off from the vacuous space, and the vacuum re-created Thus process can be carried out in various ways. The simplest and earliest form of apparatus is that described by Heinrich Geissler in 1862. This consists simply of a vessel connected by a flexible tube to an open reservoir of mercury, the vessel can by means of a two-way stopcock be connected either with the outside air or with the space to be exhausted. The stopcock being turned so as to give passage to the air, the reservoir is raised until the vessel is full of mercury; the stopcock is then turned so that the vessel is cut off from the air and connected to the space to be exhausted, and the reservoir is lowered. This tends to create a Torricellian vacuum in the vessel, into which the air from the space being exhausted rushes. The cycle can be repeated as often as desired, the fraction of air removed each time depending upon the relative volumes of space to be exhausted and the vessel.

A type of pump possessing many advantages over the Geissler pump was devised by August Töpler; it avoids all stopcocks, the connections and disconnections being made by the mercury itself. An improved form of Töpler pump is shown in fig. 3, from which the working of the pump can easily be understood. V is a cylindrical vessel connected by the tube S to the space to be exhausted. M is a mercury reservoir which must be of somewhat greater capacity than V. When the mercury levels are as in fig. 3, V contains gas at the same pressure as S. The reservoir M is then raised; the mercury rises in the tube Z, cutting off V from S, and fills the vessel V, driving the gas from it down the tube T. The gas being thus expelled, M is lowered again, and the vacuous space V is once more in connection with S The process is repeated as often as may be required. A valve at C, consisting of a glass float, the top of which is ground to fit on a seating at O, serves to prevent the mercury ever passing over into the vessel S, while the inclined position of the cylindrical vessel V has, among other advantages, that of lessening the shock of the rising mercury against the top of the vessel. Pumps of the Töpler type were widely used for producing a vacuum in the researches of the first ten years or so of the 20th century, but were then gradually superseded by rotary and other types. Pumping with them was a tedious business. By mid-20th century they were used only when it was desired to collect the gases which were being pumped out, a purpose for which they are excellently adapted.



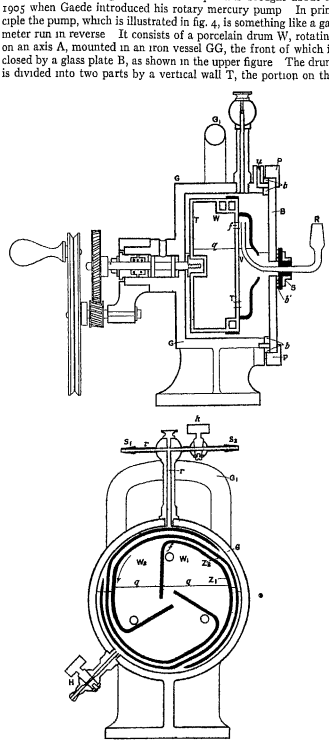


FIG 3.—THE TÖPLER MERCURY PUMP
When the reservoir M is lifted the mercury rises into the vessel V, and expels the gas down tube T. C is a float valve, seating at O, which cuts off the exhausted space

To avoid the tedious raising and lowering of the reservoir, a process which may have to be carried out for an hour or two to obtain the desired vacuum, automatic mercury pumps were devised. The earliest was that of Herman Sprengel, which consists essentially of a narrow tube down which mercury flows in a succession of drops, filling the bore of the tube, from a reservoir; the top of the tube is connected to the space S to be exhausted. If the tube is of barometric height the pressure at the top will be zero, air will pass into it from S, and will be carried down as bubbles by the mercury and discharged into a collecting vessel or into the air, as desired. This type of pump was much improved by Gimingham in 1877, and in this form used by Sir William Crookes in his ex-

tensive investigations on electrical discharges in vacuum tubes These pumps were not strictly automatic, in that the reservoir gradually emptied and had to be refilled by hand Devices were introduced by which the reservoir could be kept automatically refilled, a typical pump of this kind was that of G W. A Kahlbaum (1894), in which the flow of mercury was maintained by the help of a water-operated filter pump of ordinary type The Sprengel type of pump, which came to be extensively used, like the widely known Töpler type, was the subject of many modifications.

A revolution in high-vacuum technique was brought about in 1905 when Gaede introduced his rotary mercury pump In principle the pump, which is illustrated in fig. 4, is something like a gas meter run in reverse It consists of a porcelain drum W, rotating on an axis A, mounted in an iron vessel GG, the front of which is closed by a glass plate B, as shown in the upper figure The drum is divided into two parts by a vertical wall T, the portion on the right of this wall enclosing a space V which communicates through the tube R with the vessel to be evacuated The portion to the left of the wall is divided into three compartments by walls of the shape shown in the lower figure. The pump is filled with mercury up to the level qq When the drum rotates in the direction of the arrow the compartment W_1, which communicates with V by the hole f, is filled with gas from the receiver, while the gas in the compartment W_2, drawn from the receiver just before, is displaced by the mercury and ultimately passes into the space between the revolving drum and the casing The action is continuous It is, however, clearly necessary that the pressure prevailing in the space between drum and casing shall not exceed a few millimetres or so of mercury; the pump must therefore be run in connection with a suitable foreepump, which first reduces the pressure to a value at which the rotary mercury pump can be put in operation, and subsequently removes, as long as necessary, the gases displaced by the mercury pump. The forepump is connected to the tube S_2, the other branch S_1 being connected to a rough mercury gauge

BY COURTESY OF E LEYBOLD, KÖLN

FIG. 4.—GAEDE'S ROTARY MERCURY PUMP

As the drum W rotates, the air is displaced from the chamber W_2 into the space between drums and casing G, and is drawn from the receiver into the chamber W, through opening f. The chamber W, moves into the position of chamber W_2, and the process is repeated

With mercury pumps of this type a pressure as low as 10^{-5} mm , as measured with the McLeod gauge, can be attained There is, however, always the pressure of the mercury vapour itself, amounting to about 0.001 mm at ordinary room temperature, unless special precautions are taken to trap the vapour between pump and receiver. Moreover, the pump cannot deal with condensable vapours, such as water vapour, for the decrease of volume of the chamber during the expulsion of the gas leads to condensation of the saturated vapour in the drum. The pump requires about 40 lb. of mercury. It has, however, the advantage that it can be stopped without detriment to the vacuum already attained, which cannot be done with other types of pump to be described. The speed is about 100 cc. per second over a wide range, an exceedingly slow rate as compared with modern pumps

Aspirators and Ejectors.—When water flows through a pipe with a constricted section, the pressure in the region of higher velocity, at the narrow section, is lower than it is in the larger sections of the pipe. Because of the reduced pressure, air or other gas may be drawn into the stream through an opening in the pipe at the reduced section. This simple application of Bernoulli's principle is the basis for the water aspirator, a form of air pump usually attached to a water tap, and operated by opening the cock A side arm, with the opening into the section at reduced pressure, provides means for connection of the receiver to be exhausted A well-designed aspirator is rapid and produces a pressure of between 15 mm and 25 mm., depending on the temperature of the water, the attainable limit being the vapour pressure of the water This simplest of air pumps is useful for many operations in the laboratory that do not demand high vacuum, but it is not adapted to serving as a forepump for condensation and diffusion pumps (*see* PUMP).

In principle the steam ejector resembles the water aspirator, except that the operating fluid is steam. The gas being pumped is drawn into the high-speed jet of steam. Such an ejector, operating into atmospheric pressure, may produce a pressure of the order of 50 mm. to 100 mm. To produce lower pressure by the same means, two ejectors may be used in series, with a resultant pressure of about 25 mm to 50 mm Still lower pressure is thus attainable by adding another ejector to the series, usually with a condenser interposed between the second and third ejector This condenses the working steam from the ejectors operating at lower pressures. With three ejectors, a pressure of 0.1 mm. has been achieved; with five in series, a pressure of 0.03 mm has been reached. This is sufficiently low for many industrial uses.

If the steam ejector worked on exactly the same principle as the water pump, the lowest pressure obtainable would be that in equilibrium with steam at room temperature, or 15 mm to 20 mm. Hg That much lower pressures are obtainable is evidence that all the molecules of steam in the high-vacuum jet have been given a velocity so far in excess of their normal thermal velocity that few can return into the evacuated space.

Ejectors employing steam or oil vapour are employed as forepumps and booster pumps in modern vacuum systems.

Mercury Diffusion and Condensation Pumps.—In 1915

Gaede once again appeared with an idea for making the processes developed on the basis of the kinetic theory of gases work toward the production of a high vacuum The scheme of operation of his diffusion pump may be understood by reference to fig 5. A stream of mercury vapour passes upward in a tube which has a side branch closed with a porous plug or narrow slit through which gases may diffuse The branch connects a vessel containing air at reduced pressure. The pressure of the mercury vapour may be of the order of 1 mm , corresponding to the temperature at which evaporation occurs. Some of the vapour diffuses through the barrier into the space containing air and this, in greater part, condenses; at the same time, air diffuses in the opposite direction, where the molecules are entrained in the blast of vapour. The rates of diffusion in opposite directions depend on the respective molecular weights, the mean size of the capillary passages in the diffusion barrier, and the partial pressures on opposite sides of the barrier of the two gaseous mediums Thus the diffusion of the air into the vapour stream will continue so long as there is air in the vessel connected to the side arm, and theoretically approaches a perfect vacuum. Although the mercury continues to diffuse in the opposite direction, its vapour pressure on the right of the barrier remains low, corresponding to the low temperature of its surroundings, namely that of the cooling jacket surrounding the exhaust tube

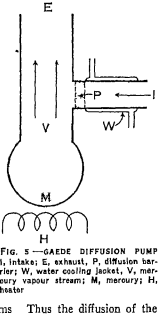

FIG. 5.—GAEDE DIFFUSION PUMP I, intake; E, exhaust, P, diffusion barrier; W, water cooling jacket, V, mercury vapour stream; M, mercury; H, heater

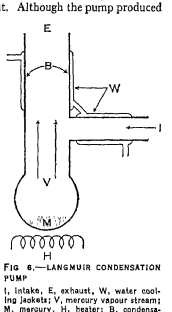
Because of the manner in which diffusion takes place in a gas, the porous plug or Gaede's equivalent of it, a narrow slit, is not necessary In Gaede's original pump, the blast of mercury vapour was made to pass a narrow slit through which the air diffused into the stream of vapour. According to his reasoning, the greatest speed of pumping was attained when the width of the slit was of the same order as the mean free path of the air molecules. The mercury vapour diffusing through the slit was immediately condensed on a cooled surface opposite the slit. Although the pump produced a vacuum higher than had heretofore been attained, its speed was slower than that of the Gaede rotary mercury pump.

By eliminating the slit and arranging for cooling of inner wall surfaces in such a manner that the mercury vapour could not diffuse back into the vessel being exhausted, or prevent the air from diffusing rapidly into the stream of vapour, Irving Langmuir greatly increased the speed of exhaust and rendered the pump less subject to variations in performance with changes in temperature of the boiler Langmuir reasoned that the mercury molecules could readily be prevented from diffusing in the direction opposite that of the air molecules by cooling the walls of the tube at a point just beyond the tube through which the air is diffusing into the vapour stream. Thus, the air molecules are rapidly carried away from their outlet, the vapour is rapidly condensed, and the temperature in the vicinity of the outlet is maintained so low that practically no mercury is re-evaporated in this region Because of the dependence upon condensation of the mercury vapour for proper functioning, Langmuir designated this type as a condensation pump, as distinguished from Gaede's diffusion pump. However, both types depend upon both diffusion and condensation for operation. Gaede's has a restricted area through which diffusion takes place, whereas Langmuir's has a large area. Modern refinements in condensation pumps have given them extremely high pumping speeds, speeds limited only by the physical dimensions that are practicable in specific cases.



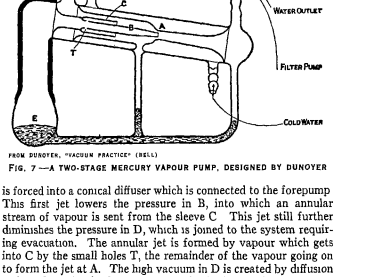


FIG 6.—LANGMUIR CONDENSATION PUMP I, intake; E, exhaust, W, water cooling jackets; V, mercury vapour stream; M, mercury, H, heater; B, condensation surfaces for mercury vapour

Mercury Vapour Pumps.—Two- and three-stage mercury vapour pumps, in which the stages are arranged in series, so that the high pressure side of one is the low pressure side of another, are made for rapid work. Since at very low pressure the mercury vapour stream loses its jet form, the stream in a diffusion pump exerts no action such as the steam jet does in an ordinary injector However, at higher pressures the Bernoulli effect comes into operation, and is utilized in the preliminary stage or stages of a multiple stage pump, where, because of the higher pressure, the diffusion principle is less effective. One of the early two-stage mercury vapour pumps as designed and built by Dunoyer which will work against a forepressure of 25 mm. or 30 mm. is illustrated in fig. 7. The first mercury jet A acts like the steam injector, and is forced into a conical diffuser which is connected to the forepump This first jet lowers the pressure in B, into which an annular stream of vapour is sent from the sleeve C This jet still further diminishes the pressure in D, which is joined to the system requiring evacuation. The annular jet is formed by vapour which gets into C by the small holes T, the remainder of the vapour going on to form the jet at A. The high vacuum in D is created by diffusion and condensation in the same way as in the Langmuir pump

FIG. 7.—A TWO-STAGE MERCURY VAPOUR PUMP, DESIGNED BY DUNOYER

Oil Vapour Pumps.—For many years mercury was the only pumping fluid used in diffusion and condensation pumps. Beginning about 1929 C. R Burch in England and K. C. D. Hickman in the United States prepared some organic oils which proved to be useful as pumping fluids Some of these have extremely low vapour pressures, a property which was exploited to obtain lower pressures. The principles underlying mercury vapour pumps are also basic to oil vapour pumps Recognizing that oils contain components which, because of their different vapour pressures, boil at slightly different temperatures, Hickman developed the fractionating pump. Two of the first practicable fractionating pumps are shown in Pl. I, figs. 2 and 4 The two-stage fractionating pump seen in Pl. I, fig 4 is made of glass and is capable of producing a vacuum of the order of 10^{-7} mm. in a closed system This is made possible by a design which by application of known principles of distillation and condensation controls the passage of oil and oil vapour through multiple boilers. After the unit has run for a short time, the extreme volatiles have been distilled into the alembics of the vertical tube. The condensed oil from the jets returns to the first boiler (boiler under the vertical tube) where the high-

est relative temperature is maintained. The more volatile constituents in the oil are vaporized and stream from the jet. The material of lower vapour pressure passes through the connecting tube to the second boiler. The second stage produces better vacuum at high speeds because the oil which reaches it has been rectified in the first stage; *i.e.*, fractions of higher vapour pressure have been eliminated. The small boiler at the end of the pump serves as a still in which the dark-coloured nonvolatile residue collects while the more active components are distilled and returned to the other two boilers by the overhead glass tubes leading to these boilers The addition of another boiler and jet as seen in Pl I, fig 2 broadens further the use of the principle of fractionation and realizes the ultimate possibilities of oils as pumping fluids

A metal fractionating oil pump is illustrated in Pl I, fig. 3, and in fig. 8. This pump is not so efficient in fractionating the oil as is the horizontal glass pump described above but it does afford considerable self-conditioning of the pumping medium, is robust, compact and capable of reaching pressures of 10^{-6} mm. and lower. This design of pump may be built in different sizes resulting in a series of pumps with a wide range of pumping speeds.

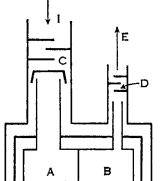

FIG. 8.—SECTION OF AN ALL METAL, TWO-STAGE, FRACTIONATING PUMP

I, Intake; E, exhaust; C, high vacuum section; D, forevacuum section; A, high vacuum boiler; B, forevacuum boiler; L, pumping fluid; H, heater

The boiler of this pump is divided into two sections, A and B in fig 8. The high vacuum section C has an umbrella jet and the forepressure section D has an upright jet There are baffles in each section above these jets to provide cool areas for oil vapours to condense on and be returned to the boilers The two stacks of this pump may be either air-cooled or water-cooled The stacks in Pl. I, fig. 3 are air-cooled; external fins enlarge the cooling surface. In the forepressure boiler B there are small dams making the oil pass over a longer path enabling the more volatile constituents to evaporate in this boiler and allowing the less volatile constituents to get over to the high-vacuum boiler which serves the high-vacuum jet

Similar to the multijet mercury diffusion pumps, oil diffusion pumps may be made as nonfractionating one-, two- or three-jet types However, most oil pumps are designed to produce some partial fractionation of the oil, since the employment of this principle always results in a more efficient pump. In a three-stage oil diffusion pump, as shown in Pl. II, fig 3, the condensed vapour enters the circular boiler from the outside edge. The chimney is common to the three jets, supplying the jets with vapour in a manner similar to the mercury vapour condensation pump previously described. There is built into the forepressure arm a series of alembics for collecting the highest volatile substances and preventing their return to the pumping fluid In another type of upright, three-jet oil diffusion pump, there are three separate concentric chimneys for the three jets. The outside chimney feeds the lowest vacuum jet and the inside, the highest. The condensed vapour enters from the outside edge into the boiler and on its passage to the centre chimney the higher volatiles are boiled off into the higher vacuum jets This results in a semifractionation of the oil.

The pumping speeds of mercury vapour and oil vapour pumps range from 1 l. per second up to many thousands of litres per second at 10^{-4} mm. and under proper conditions will attain an ultimate pressure of 10^{-7} mm

Booster Pumps.—With the development of the oil diffusion pump, certain limitations in its use were soon discovered. Although higher speeds at lower pressures were obtainable because of improved pump construction and lower vapour pressure of the oils, it was noted that the pressures into which the oil diffusion pump would satisfactorily discharge the gases were comparatively lower. Another way of stating the same thing is that the forepressure breakdown, or pressure into which or against which the oil diffusion pump would operate, was low. This resulted in low speeds in the regions of pressure between the optimum working pressure for the mechanical pump and the optimum forepressure for the high speed diffusion pump. To overcome this difficulty it was necessary to develop another type of pump which would discharge into a region of comparatively high forepressure These pumps are known as "booster pumps" (Pl. II, figs 1, 2 and 4) They operate on the diffusion-condensation and jet ejector principles and will maintain a low pressure into which a high-speed diffusion pump may exhaust.

Measurement of Low Pressures.—*Vacuum Gauges.*—Pressures down to a few millimetres of mercury can be measured by an ordinary mercury manometer, consisting of a U-tube having one side closed at its upper end and filled with mercury. When the other branch is connected to the vessel in which the pressure is to be measured the difference of level in the two branches, which may be read with vernier attachments or with a cathetometer, indicates the excess pressure in the vessel above the Torricellian vacuum in the closed branch Such manometers are commonly used for rough readings, since, in the vacuum range of 1 mm and less, this small difference in levels cannot be measured with great accuracy. A more sensitive mercury manometer is one in which the two mercury surfaces are kept precisely in contact with fine vertical pointers. The difference of pressure is measured by the angle through which it is necessary to tilt the manometer in order to restore the level when it is disturbed by the presence of gas on one side. This gauge has been used to measure pressures from 1 5 mm. to 0 001 mm. Another way of measuring very small displacements of the mercury surface in a U-tube manometer is by means of a little float on the surface supporting one end of a lever carrying a small mirror; the tilt of the mirror is measured by a lamp and scale.

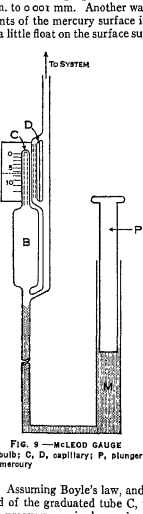

FIG. 9.—MCLEOD GAUGE

B, bulb; C, D, capillary; P, plunger; M, mercury

The first successful special device for measuring pressure too low to be accurately measured by the ordinary U-tube manometer was the gauge invented by McLeod in 1874, and known by his name. It consists in principle of a bulb B, some 250 cc in capacity, provided with a fine calibrated vertical capillary C, fig. 9. The mercury surface can be adjusted to any desired height by the device of a mercury reservoir with displacement plunger P connected to the apparatus. The bulb B is connected to the space in which the pressure is to be measured. The mercury surface is raised, cutting off a known volume of gas, at very low pressure, in B, and then forcing it into the capillary C. The pressure which the amount of gas present exerts in this confined space is then observed. To avoid error due to capillarity in measuring the pressure a side-tube D is provided of exactly the same bore as C, and the difference of levels h in C and D measured. The level in D is opposite the top of the capillary C. Assuming Boyle's law, and knowing the volume of the bulb B and of the graduated tube C, the original pressure in B, which is the pressure required, may be calculated from $p = ah^2/V$, where p is the pressure of the gas in mm., a is the cross section of the capil-

lary C, h is the head of mercury which is compressing the gas (difference of level in C and D) and V is the combined volume of the bulb B and the capillary C.

The McLeod gauge was by mid-20th century the standard instrument for the accurate measurement of pressures down to 10^{-6} mm. with certain gases and proper precautions. Many other types of gauges are calibrated using this gauge as the standard of reference. The accuracy of the gauge depends upon the closeness with which the gas in question obeys Boyle's law, perfect compliance with which is assumed in the deduction of the equation for the pressure. The gauge cannot be used with condensable vapours, such as those of water or ammonia, which tend to liquefy on the walls, even with carbon dioxide the readings are not reliable With such gases as hydrogen and nitrogen, on the other hand, the gauge works down to its limit of pressure measurement.

Since McLeod gauges cannot be used with such gases as chlorine, which are chemically very active and attack mercury, various types of membrane manometer have had to be devised. Very thin spiral glass tubes, working on the principle of the Bourdon gauge used for steam pressures, have been used for such gases, the displacement of the end of the spiral being measured with mirror and scale Such gauges are not sensitive to pressures less than about 0·1 mm. The mechanical deformation of a very thin metal or glass membrane has been used to measure small pressures One side of the membrane is exposed to the gas or vapour, while on the other side the vessel is evacuated by a high-vacuum pump. The very small movements produced are measured by an interference method, and results have been obtained down to 0·001 mm., but the instrument is difficult to manipulate

The exceedingly low pressures produced by modern techniques have led to the construction of a whole class of new manometers, depending for their operation on the behaviour of gases at low pressures; *i.e.*, the behaviour of gases when the mean free path of the molecule is comparable with the linear dimension of the vessel The thermal conductivity and the viscosity are properties which are independent of the pressure so long as the mean free path is small, but change rapidly with the pressure when the pressure is very low, becoming proportional to the pressure below a certain value of pressure, depending upon the nature of the gas and the dimensions of the vessel. Again, at low pressures, the radiometer effect manifests itself; that is, there is a mechanical repulsion between a warm surface and an opposing colder surface when gases at low pressure lie between them Further, with simple forms of triode vacuum tubes, as long as (1) the pressure is low enough for the electrons to have a free path greater than the distance between the hot wire and the surrounding grid and (2) the potential fall accelerating the electrons which is well above the ionization potential of the gas, the ionization produced between the grid and the surrounding cylinder is proportional to the pressure. All these effects have been utilized in the construction of special low-pressure gauges.

Two types of viscosity gauges may be mentioned In one, devised by Langmuir and Dushman, a very light horizontal disk of mica hangs suspended by a quartz fibre directly above a second horizontal disk This second disk is carried on a vertical shaft which can be set in rapid rotation by a rotating magnetic field outside the glass vessel. The drag of the rotating disk on the suspended disk, which is proportional to the speed of rotation and to the pressure of the gas between the disks, is measured with the aid of a mirror attached to the suspended disk. The effective viscosity depends not only upon the pressure but also upon the nature of the gas, so that the gauge requires special calibration. Because of secondary effects this gauge is not reliable at extremely low pressures, and on account of the lack of proportionality between drag and pressure it cannot be used at pressures above 0.02 mm. Hg. The gauge has not found wide use.

A much simpler form of viscosity gauge, developed by Langmuir, consists merely of a vertical quartz fibre, rigidly fastened at the upper end to the top of the vessel. When the vessel is tapped, the fibre is set in vibration, the amplitude of which decreases at a rate determined by the pressure of the residual gas in the vessel. The gauge can be used down to pressures of 10^{-4} mm. Hg.

The Pirani gauge is based on the physical principle that the thermal conductivity of a gas is related to its pressure by the approximate relation, $K = C \times p$, for pressure below values where the thickness of the gas layer is of the order of the mean free path K is the thermal conductivity of the gas, p its pressure and C is a constant The thermal conductivity is indirectly measured by ascertaining the change with pressure in the resistance of a hot filament in the vacuum chamber. As the pressure about the filament alters, so the speed at which heat is conducted away from the filament changes The heat is conducted away from the filament by molecules of gas colliding with the filament and, in turn, colliding with cooler surrounding surfaces. The more of these collisions (higher pressures) the greater the cooling effect on the filament and hence the lower resulting temperature of the filament. The change in temperature effects a change in the resistance. These resistance changes are measured by a Wheatstone bridge arrangement, fig. 10 The filament used should be of a metal with as high a variation in resistance with temperature as possible; tungsten and platinum wire and a "thermistor" unit are satisfactory in this respect

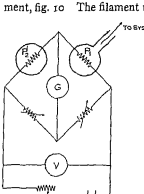

FIG 10.—PIRANI GAUGE

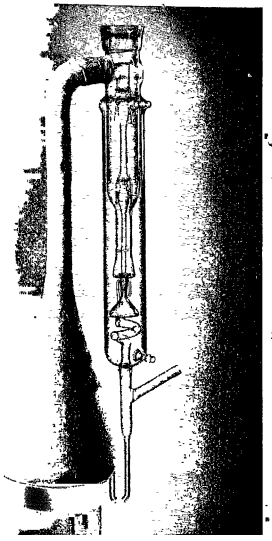
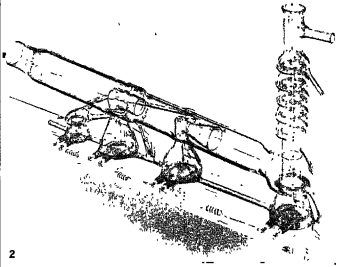
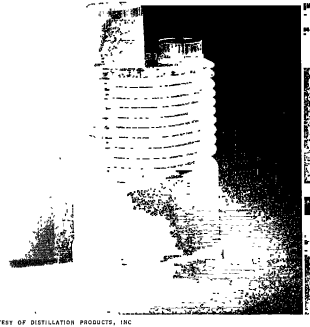
In fig 10, P_1 is the gauge filament which is enclosed by a housing attached to the vacuum system, P_2 is an identical filament whose housing has been evacuated to an extremely low pressure. The instrument has to be calibrated against a McLeod gauge.



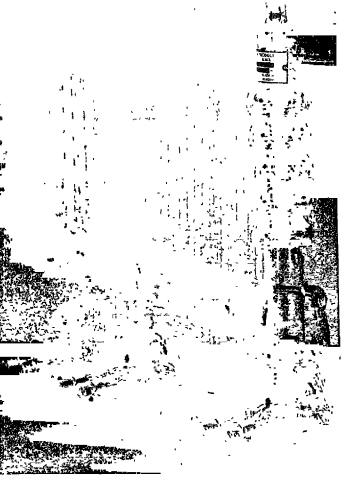
The total pressure is indicated by the gauge, *i.e.*, it shows the pressures of condensable gases and vapours, for example, water vapour. Unfortunately the heat loss of the filament is determined by the nature of the gas molecule and so the gauge can be accurately calibrated for only one particular gas. It is very important, therefore, to avoid the introduction of water or other vapour when measuring air pressures However, despite this fault it has the virtue that it will indicate the presence of unsuspected vapours which the McLeod gauge would completely fail to reveal. The other advantage is the ability to indicate the pressure instantaneously and continuously.



The useful range of the Pirani gauge is from 10^{-1} mm. to 10^{-4} mm This gauge is widely used



Another conductivity gauge is the thermocouple gauge, which, in operation, closely resembles the Pirani gauge, and is subject to the same operating conditions. It differs from the Pirani gauge in its utilization of thermoelectromotive force in place of change of electrical resistance as the actuating means A thermoelectric junction of small dissimilar wires, fig. 11, is supported inside a glass bulb. A small heating element, spot-welded to the junction, is also supported inside this same glass bulb. The bulb is joined to the system in which the pressure is to be measured. A current of the order of 0–100 milliamperes is passed through the heating element. The thermoelectric current developed is measured by a sensitive meter. Since the temperature attained by the junction depends on the conductivity, and hence on the pressure, the surrounding gas pressure is indicated in terms of meter deflection, and the scale of the meter may be calibrated in pressure units if desired The useful range of the gauge is between 10^{-1} mm. and 10^{-4} mm.



The ionization gauge, fig. 12, in its usual form is similar to a three-element vacuum tube. The electrons from a heated filament are accelerated toward a collecting electrode which may be either the grid or the plate of the tube. The positive ions formed through bombardment of gas molecules by this electron stream are collected on the third electrode; *i.e.*, on the plate if the electron current is collected on the grid. The positive ion current varies with the pressure in the region of the grid and plate.

In fig. 12 the grid is the electrode which collects the electron current. The grid is positive with respect to the filament and nega-

tive with respect to the plate Some of the electrons after receiving energy caused by the voltage drop between the filament and the grid pass through the grid openings into the region between the grid and the plate In this region the electrons bombard gas molecules and produce positive ions which migrate to the plate. The equivalent current is read on the microammeter

In a second arrangement the plate is positive with respect to the filament and the grid is negative The negative plate arrangement is the more sensitive method but the procedure when using the negative grid is the easier

The electron or filament emission current is about 10 milliamperes whereas the ionization current is about 50 microamperes. Below 10^{-4} mm. the pressure is directly proportional to ionization current With the emission of 10 milliamperes the plate voltage needs to be about −20 v and the grid voltage of the order of 200 v For given pressure, anode voltage and anode current, the ionization current is proportional to the number of free electrons in the gas Thus the gauge is selective and needs to be calibrated for each gas used The lowest pressures attained, of the order of 10^{-8} mm, have been measured with an ionization gauge. The extremely low limit of pressure capable of being measured with it is the great advantage of the gauge. The two principal disadvantages of the gauge are its low maximum pressure reading, and the fact that it needs calibration for each gas used By the same token, for accuracy of reading, vapours must be excluded Because of possible oxidation of the hot tungsten filament the gauge should not be operated above 10^{-2} mm

Calibration is done by means of the McLeod gauge Great care needs to be taken to ensure purity of gas and equality of pressure throughout the system during this calibration.

The cold-cathode ionization gauge, fig. 13, uses a cathode glow-discharge as the means for ionizing the gases in the envelope of the gauge tube. A permanent magnet is used in some designs of cold-cathode gauges to increase the length of the electron-molecule collision path. The electrons ejected from the surface of the cathode by the high potential gradient at the cathode ionize the gas in the gauge envelope. The electrons resulting from this ionization are either collected by the anode and the resulting cathode-

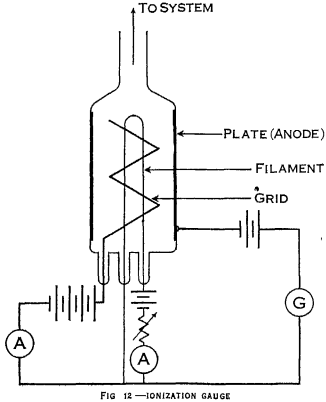

FIG 12 —IONIZATION GAUGE

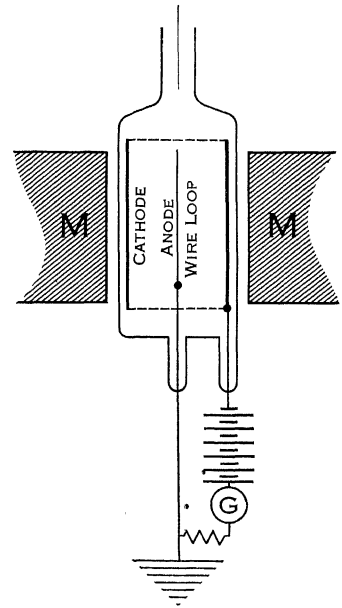

FIG 13 —DISCHARGE IONIZATION GAUGE

anode current measured by a sensitive meter or the electrons produce further ionization which results in more electrons. The additional electrons are collected by the anode and the total electron current measured. There is a proportionality between number of gas molecules and electron current produced by ionization.

In some designs of the cold-cathode gauge the electron paths from cathode to anode are made several hundred times longer than the direct path by applying a magnetic field across the tube causing the electrons to move in a spiralling or sinuous path. Increasing the travel of the electron will, in proportion, increase the probability of an electron ionizing the molecules of the residual gas, and so an ionization current is obtained several times greater than would prevail if the electrons travelled in straight lines from cathode to anode impelled by the electric field only. Since the cold-cathode gauge does not depend upon a hot tungsten filament for its operation it may be used at higher pressures than the hot-filament ionization gauge. Also, it cannot measure extremely low pressures The range of the cold-cathode ionization gauge is from 0 0001 mm to 0 003 mm. Opening the gauge to atmospheric pressure does not harm it

Fig 13 shows the electrode and circuit arrangement for the cold-cathode ionization gauge with magnetic field The anode and cathode are shown in their relative positions. Magnet M maintains a strong magnetic field The voltage across the tube is of the order of 2,000 v. D.C and the magnetizing field around 400 oersteds. The cathode is made of zirconium, thorium or other material giving a copious supply of electrons under the "cold" discharge The gauge should be calibrated against a McLeod gauge for each gas used This gauge coupled with the Pirani or thermocouple gauge makes a very useful combination because the two cover the range from a few millimetres to approximately 10^{-4} mm. pressure.

A third type of ionization gauge, in many ways like the cold-cathode gauge, is the alpha-ion gauge Ionization of the gas molecules in the gauge is accomplished by the alpha particles which are discharged at constant rate by a radium source. The radium is sealed into the gauge housing. The range of this gauge is from 0 001 mm. to 10 mm. It extends to higher pressure ranges than the cold-cathode gauge and also is not damaged by opening to atmospheric pressure Calibration of the cold-cathode and alpha-ion gauge is made using a McLeod gauge as the reference.

The Knudsen gauge provides continuous readings from 10^{-2} mm. to 10^{-7} mm It is an absolute gauge and needs no calibration against a McLeod. The gauge consists of an aluminum vane suspended from a fine tungsten wire within a metal casing, fig. 14. The deflection of the vane is measured by an optical system in which a beam of light is reflected onto a translucent scale from a small mirror attached to the vane. Two electric heaters are located parallel with the vane on opposite sides near the edges, so that gas molecules accelerated by the heaters strike the vane, causing it to rotate. The amount of rotation is proportional to the pressure, other conditions remaining constant, and the distance between the vane and heaters being small in comparison to the mean free path of the molecules at the existing pressure The damping magnets eliminate erratic movement of the vane caused by normal vibration without appreciably affecting its sensitivity.

The equation for calibration of the Knudsen gauge is given by

$$P=\left(\frac{2\pi^2 I}{rA\beta^2}\right)\left(\frac{D}{d}\right)\left[\frac{1}{\left(\frac{T_1}{T}\right)^{\frac{1}{2}}-1}\right]$$

If T_1 and T are fairly high temperatures on the absolute scale, and if their difference is small,

$$P=\left(\frac{4\pi^2 I D}{rA\beta^2 d}\right)\left(\frac{T}{T_1-T}\right) \text{dynes per square centimetre}$$

where: I = moment of inertia of moving vane
r = mean radius of moving vane
$2A$ = total area of the vane opposite heaters
t = period of oscillation of the vane
D = scale deflection
d = scale distance

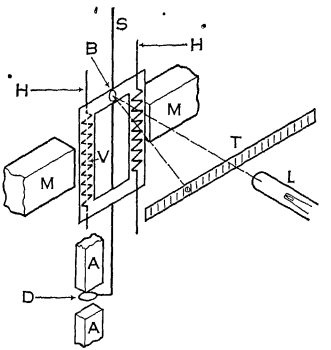

Fig 14 —THE KNUDSEN GAUGE

S, tungsten wire, H, heater, A, internal damping magnet, B, mirror, D, damping vane, M, external damping magnet, V, impact vane, L, lamp, T, scale

T = absolute temperature of residual gas in gauge
T_1 = absolute temperature of heating elements H.

Since all these quantities can be measured directly, it follows that the device can be used as an absolute manometer, without the necessity of calibrating against any other gauge It is also evident that the indications of this gauge must be independent of the gas to be measured.

Pumping Speed.—In the preceding discussion three principal types of vacuum pumps—the oil-sealed mechanical pump, the diffusion pump and the booster pump—have been described. Usually some combination of two of these pumps is needed and there are occasions where all three types together constitute the pumping unit for the vacuum system.

One important characteristic of any pump is its pumping speed. The speed of exhaust of a closed vessel may be measured at constant pressure, and defined as the volume of gas pumped from the vessel at that pressure in unit time. Expressed mathematically

$$S_1=-\frac{dV}{dt}$$

where S_1 is the pumping speed and dV is the small change of volume in the short time dt By applying Boyle's law for a perfect gas this definition may be written as

$$\frac{dp}{dt}=-\frac{S_1}{V}p$$

where p is the instantaneous pressure at the time t in a closed volume V being exhausted by a pump having a speed S_1. In 1913 Gaede published some of his work with vacuum pumps, which indicates that he originated the concept of pumping speed. In 1916 Langmuir introduced the concept of limiting pressure p_0 for a pump which modifies the Gaede equation by substitution of $(p-p_0)$ for p. The equation above then becomes

$$\frac{dp}{dt}=-\frac{S_1}{V}(p-p_0)$$

The solution of this modified equation is

$$t_2-t_1=\frac{2}{S_1}3V[\log_{10}(p_1-p_0)-\log_{10}(p_2-p_0)]$$

where t_2-t_1 is the time required to reduce the pressure in the volume V from p_1 to p_2 using a pump of speed S. It should be noted that the vessel being evacuated is connected directly to the intake of the pump. Pump speed S_1 is the pumping speed

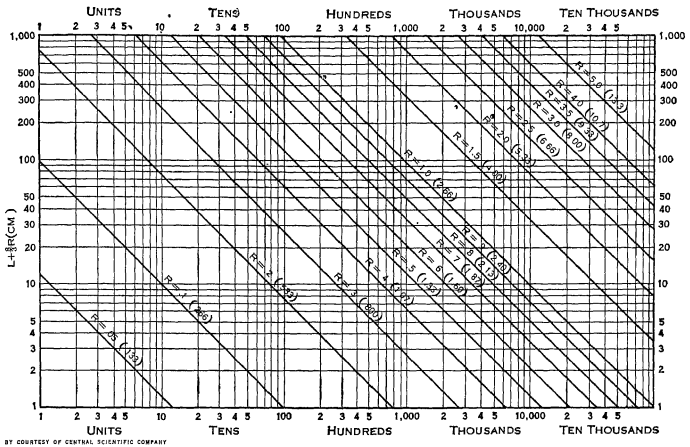

FIG 15.—CHART OF CONDUCTANCE OF CONNECTING TUBES FOR AIR AT LOW PRESSURE

at the pump intake

Usually a connection of some length is required between the pump and the vacuum chamber. Under such circumstances the pump speed S_1 is not the controlling factor. In making "pump-down" calculations, particularly if pressures below 10^{-2} mm. are involved, the speed of evacuation S rather than pump speed S_1 determines the period of cyclic operations.

When the pump is operating in the high-vacuum range, the flow of gas through a tube is substantially molecular in character. The hydrodynamic component of gas flow, being proportional to pressure, becomes relatively unimportant. In other words, at extremely low pressures the gas removed from the system is largely confined to those molecules which, because of their thermal kinetic energy, happen to wander into the low pressure region created by the pump, and by the action of the pump become trapped and prevented from again entering the chamber being evacuated

From experiments over a large range of pressures with different gases, Knudsen in 1909 derived the following semiempirical relation which holds at all pressures.

$$Q=\left[aP+Z\frac{(1+\alpha P)}{(1+\beta P)}\right](p_1-p_2)$$

Where $a=\dfrac{\pi R^4}{8\mu L}$ (coefficient of hydrodynamic flow—Poiseuille's constant)

$$Z=\frac{\sqrt{2\pi}}{\rho'}\frac{4}{3}\frac{R^3}{L}\text{ (coefficient of molecular flow)}$$

$$\alpha=\frac{2\sqrt{\rho'}R}{\mu}$$

$$\beta=\frac{2.47\sqrt{\rho'}R}{\mu}$$

where Q = volume of gas, measured at pressure P, which flows per second through the tube

p_1-p_2 = difference in pressure at the two ends of the tube

$P=\dfrac{p_1-p_2}{2}$ = average pressure

R = radius of tube

L = length of tube

μ = coefficient of viscosity of the gas

$\rho'=\dfrac{\rho}{P}$ where ρ = density of the gas

ρ' is a function only of the kind of gas and the temperature.

For ordinary pressures this equation assumes the form commonly known as Poiseuille's law,

$$Q=\frac{\pi R^4}{8\mu L}P(p_1-p_2)$$

while at extremely low pressures it becomes

$$(1)\quad Q=\left[\frac{\sqrt{2\pi}}{\rho'}\frac{4}{3}\frac{R^3}{L}\right](p_1-p_2)$$

The quantity enclosed by brackets in the above equation is a factor applying only in the case where one is considering the quantity of gas, Q, flowing per second through a tube of length L and radius R with a difference of pressure at the ends of p_1-p_2 Effects of the various end conditions that may be applied to the tube have not been considered. Hence where we have a tube of length L and radius R connecting two vessels at low pressures, the quantity of gas Q flowing per second from the vessel at pressure p_1 through the tube into a second vessel at pressure p_2 is given by

$$(2)\quad Q=\left[\frac{4}{3}\left(\frac{\sqrt{2\pi}}{\rho'}\right)\left(\frac{1}{\dfrac{L}{R^3}+\dfrac{8}{3R^2}}\right)\right](p_1-p_2)$$

It will be observed that the form of the last two equations is similar to Ohm's law, where Q is similar to a current, (p_1-p_2)

similar to a potential drop and the bracketed term similar to a conductance. It must be remembered that the bracketed term in the equation (1) considers only the gas flowing through a tube, neglecting end effects. For a long tube this is sufficiently accurate in most cases. The bracketed term in equation (2) is for the case of a tube terminating at a thin wall, the circular opening in the wall being of the same diameter as that of the tube. This expression for the conductance has been used in plotting the curves shown in fig. 15 Other types of end configurations would introduce other correction factors into these equations. For different gases the value of the conductance varies as the reciprocal of the square root of ρ'.

Some of the references given in the bibliography give further discussion to the problem of flow of gases in pipes at low pressures.

The system speed of evacuation S is related to the speed of the pump S_1 and the conductance of the connecting tubing Z by the following relationship.

$$\frac{1}{S}=\frac{1}{Z}+\frac{1}{S_1}$$

On rearranging the terms,

$$S=Z\left[\frac{S_1}{Z+S_1}\right]=S_1\left[\frac{Z}{Z+S_1}\right]$$

These expressions have important significance The fractional term in either expression is less than 1. Consequently, the speed of evacuation S can never be greater than the conductance Z nor can it be greater than the speed of the pump S_1 The second expression suggests that the speed of evacuation approaches the speed of the pump only when Z is very large in comparison with S_1. This expression shows that the performance of a high-speed pump may be seriously impaired by the use of ill-chosen connections. For a well-designed pipe line, pumping speed (speed of evacuation) S in a system should not be much less than 80% of the speed S_1 at the intake of the pump.

When several lengths of tubes of different diameters are connected in series between the pump and exhaust chamber the conductance Z for the combination is given by

$$\frac{1}{Z}=\frac{1}{b_1}+\frac{1}{b_2}+\frac{1}{b_3}+\ldots+\frac{1}{b_n}$$

where b_1, b_2, etc. are the respective conductances of the tubes.

Traps or Condensers.—A trap is an obstruction placed in a vacuum system for the purpose of collecting solid particles, liquids, vapours or gases. If vapours are involved, the trap must be cooled The cooling may be done by mechanical refrigeration, by a mixture of solid carbon dioxide (dry ice) and alcohol or acetone, or by liquid air. Typical traps are shown in fig. 16. Certain "permanent" gases may be removed by using a trap of activated charcoal cooled with liquid air.

The conductance of a trap in the vacuum system may be quite important Hence traps are preferably constructed with large passages to avoid undesirable reduction in pumping speed.

Refrigerated glass traps are commonly used between a McLeod gauge and the vacuum system to prevent contamination of the mercury and the glass parts of the gauge and to prevent diffusion into the vacuum system of mercury vapours from the gauge. Such a trap is also frequently used between the pump and the vacuum system, either to trap vapours which might contaminate the pumping fluids, or to prevent passage of oil vapours from the pump into the vacuum system.

MANAGEMENT OF THE VACUUM SYSTEM

In industrial use, high vacuum is considered to begin in the range of pressures corresponding to 1 mm. Probably this would not be considered high vacuum by the experimental or research man working in the laboratory where pressures of the order of 10^{-3} mm. are obtained. Attainment of a good vacuum requires thoughtful selection of equipment, care in assembly and manipulation of the apparatus.

The elements of a vacuum system have been discussed in the preceding sections. They consist of forepump, diffusion pump,

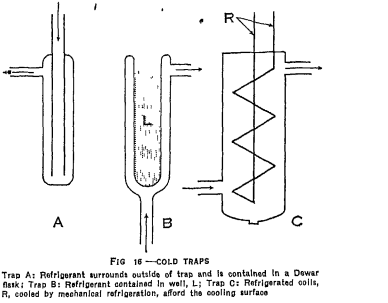

FIG 16.—COLD TRAPS

Trap A: Refrigerant surrounds outside of trap and is contained in a Dewar flask; Trap B: Refrigerant contained in well, L; Trap C: Refrigerated coils, R, cooled by mechanical refrigeration, afford the cooling surface

cold traps, valves, plumbing, gauges and the apparatus or equipment to be evacuated A number of factors must be considered in selecting a pumping system. The choice will be largely influenced by the arrangement of the equipment, the volume of the vacuum chamber, the quantity of gas to be handled at low pressures and the importance of time in cyclic operations. One consideration that is generally common to various arrangements is the speed of the forepump. This is directly related to the speed of the diffusion pump and the ratio of pressures at the discharge and intake of the diffusion pump. On the assumption that a particular diffusion pump has a speed of 100 l per second at 10^{-6} mm. and that the pump operates satisfactorily at a fore-pressure of 10^{-2} mm, the ratio of pressures is 1 to 10,000. This means that a forepump capable of handling 0 0001 of 100 l. per second or 0 01 l per second is theoretically sufficient for the job This suggests that a relatively low-speed forepump would be sufficient. However, there are usually other factors that must be considered

Fluids used in diffusion pumps often deteriorate if their temperatures are elevated when in contact with air at pressures of 0.1 mm and above. Unless appropriate steps are taken, this means that a certain amount of time is lost in heating and cooling the boiler in a cyclic operation To avoid this loss of time, various techniques are used. In some instances, two parallel pumping systems are installed. One consists of a high-speed forepump either directly connected or connected through a cold trap to the vacuum chamber and a second independent connection in which a relatively small forepump backs a diffusion pump During the preliminary pumping period or when air is admitted to the vacuum chamber the intake to the diffusion pump is closed but all the pumps are permitted to operate. In operation the high-speed forepump withdraws the air from the chamber to the low millimetre range after which the diffusion pump is opened to the system so that the reduction in pressure continues without interruption In another arrangement only one forepump is used. More vacuum valves are required because the high-speed forepump is first connected to the vacuum chamber and later placed in series with the diffusion pump

Valves and plumbing must be free from leaks and of high conductance. The question of system speed (speed of evacuation) has been discussed and the methods for calculating conductance outlined. As part of the steady improvement in vacuum techniques, by which the lower limit of pressure has been pushed steadily downward, it became increasingly important to detect and locate even the microscopic leak in the walls of the vessels, connecting tubes, junctions of parts, all of which constitute the barrier between a region of high vacuum and one of atmospheric pressure. The final vacuum attained in a system is an equilibrium condition between pumping speed, on the one hand, and the rate of leak into or evolution of gas within the system, on the other.

Various methods of leak detection have been employed. With the rapid advances in vacuum techniques made during World War II many new methods were developed. Older methods employ the Tesla coil, discharge tube, Pirani and ionization gauges. Newer methods make use of the differential Pirani gauge and the mass spectrometer. Oddly enough, the most sensitive method is also the most rapid; *i.e.* the mass spectrometer method

Vacuum systems are constructed from glass and metal. Depending upon the conditions a system may be either all glass or all metal. Glass can be easily cleaned and welded at junctions. It has high electrical insulating quality, may be baked out and sealed off to give a more or less permanent vacuum. Metal systems are made from steel or brass. The parts may be machined and fitted together with rubber gaskets or soft-soldered, silver-soldered or brazed. Glass or metal vacuum valves can be fitted permanently or with tapered joints, into the system.

Where the highest degree of vacuum is desired considerable outgassing of glass and metal parts must be done. Outgassing removes gases adsorbed to the surface of glass and metal. Prolonged heating of glass at 150° C. to 200° C. in vacuum removes most of the gases adsorbed on the surface, metals strongly heated in a vacuum give off adsorbed gases as well as absorbed gases and gas arising from the decomposition of oxides near the surface. Metal parts within the evacuated chamber are outgassed by heating to a high temperature with high frequency induced currents. When an apparatus has been reduced to its lowest pressure by continued pumping and heating and is sealed off from the system, the pressure may be further lowered by a getter. Getters remove gases by chemically combining with them and by absorbing them.

Further detailed information on procedures in the management of high vacuum systems will be found in the references given in the bibliography.

HIGH-VACUUM COMMERCIAL APPLICATIONS

High vacuum as employed in industry generally falls within two ranges of pressures:

(a) 1 to 1000 μ (1 μ = 0.001 mm Hg.),

(b) 10^{-3} mm. to 10^{-3} mm Hg.

The extremely low pressures are found almost exclusively in the electronics industry, while pressures in the micron range find applications throughout the chemical and metallurgical fields. By undertaking processes under an appropriate range of gas pressures, one or more of the following advantages may be gained. (1) oxidation is prevented, (2) distillation temperature is reduced, (3) absorbed and adsorbed gases may be removed, (4) dehydration may be performed at low temperatures, (5) gaseous ionization may be prevented or controlled, (6) thermal conduction of gases may be reduced, (7) radiant energy absorption may be reduced.

Vacuum Metallurgy.—The use of free air pressures below 100 μ has found many applications in the production, purification and treatment of metals.

Thermal Reduction.—Metal oxides may be reduced under vacuum and distilled from the hot reaction zone in highly purified form. Magnesium has been commercially produced from calcined dolomitic limestone by the following reaction:

$$2(MgO\ CaO) + \tfrac{1}{3}FeSi_2 \xrightarrow{2,150^\circ F} 2Mg + (CaO)_2SiO_2 + \tfrac{1}{3}Fe\ .$$

With appropriate reducing agents other metals such as calcium, lithium, barium, caesium, rubidium, sodium, and potassium may be produced in pure form from their salts

Distillation of Metals.—Through the use of pressures of 1 to 100 μ the lower melting metals (magnesium, zinc, lead, tin, cadmium, lithium, barium, etc.) may be purified by distillation. Impure magnesium as formed by the carbothermic process has thus been distilled in vertical electrically heated retorts, of several-ton capacity. Separations of lighter melting metals by fractional distillation (*i.e.*, zinc and tin or zinc and aluminum) has also been accomplished

Vacuum Sintering.—This technique is employed chiefly in the production of tungsten, molybdenum, tantalum and columbium. Bars of the pressed powdered metal are electrically heated in vacuum and after sintering, rolled to size.

Heat Treatment.—Through the use of a vacuum furnace, dies, tools, etc., may be heat-treated without the usual oxidation, the vacuum serving as a true neutral atmosphere

Vacuum Melting.—Dissolved gases may be removed by maintaining metals above their melting point at low pressure. Gas-free metals, particularly copper and iron, are useful in the electronics industry for the fabrication of parts sealed in vacuum. Copper so treated has greatly increased ductility and improved thermal and electrical conductivity. Highly reactive metals like titanium have been melted and cast at air pressures of 10 μ.

Vacuum Dehydration.—Vacuum evaporation is commonly used in the chemical industry for the removal of water or other solvents from many products. By the use of extremely low air pressures (*i.e.*, less than 10 μ) moisture can be rapidly removed from heat-sensitive materials.

Three pumping methods are normally employed for the removal of water vapour at low temperatures: steam ejectors, refrigerated condensers and chemical absorption systems. In the case of steam ejectors, partial air pressures below 50 μ are feasible on a commercial scale and very large volumes of water vapour may be handled at slightly higher pressures. In other systems, the free air is removed with steam ejectors or mechanical pumps, alone or in combination with oil diffusion pumps. The water vapour is then (a) condensed or (b) absorbed. Free air pressures as low as 1 to 10 μ are possible and under such conditions moisture can be removed at temperatures in the product as low as −75° C.

The possibility of low-temperature drying has been applied for many years to the preservation of biological products on a small scale. It was only after recent advances in vacuum engineering that low-temperature high-vacuum dehydration was applied on a commercial scale.

Blood Plasma.—In order to prevent changes in composition, and to preserve a so-called lyophilic structure capable of rapid rehydration, blood plasma is vacuum dried from the frozen state.

Biologicals, etc.—Low-temperature drying has also been applied to penicillin, sera, vaccines, bacteria, nerves, etc.; through the use of the very low temperatures made possible by high vacuum, cellular structure may be preserved throughout the drying cycle and the biological properties maintained after reconstitution even though the product in dried form is stored for long periods.

Foods.—The vacuum dehydration of food products had, by 1951, offered one of the most promising solutions to the production of a high-quality product. The original structure may be maintained, flavour and colour are relatively unimpaired, and sufficiently low moisture content may be produced (0.5% to 1%) to ensure a satisfactory storage life. Because of the relatively high costs involved, vacuum dehydration at air pressures in the micron range has been applied to such relatively expensive materials as orange juice and soluble coffee. The vacuum process for producing a 4:1 concentrate of frozen orange juice had by 1950 become a $100,000,000 a year business. Vacuum drum driers operating at moderate vacuums (10 mm. to 50 mm.) are used for a variety of products such as tomato paste, soups, coffee, etc.

Vacuum Evaporation.—Through the use of pressures below 10^{-4} mm., a variety of metals and salts may be evaporated and their vapours subsequently condensed on a surface.

Low-Reflection Coatings.—So-called low-reflection coatings are

produced by evaporating magnesium fluoride, or material of comparable refractive index, in a vacuum system and depositing the vapour to a controlled thickness (one-quarter of a wave length) on a lens or other optical surface

Reflecting Surfaces.—This same technique may be used to produce front surface mirrors on glass, plastics or other material Aluminum is commonly employed and evaporated from a heated tungsten filament. Chromium, gold, rhodium, silver, etc., are also used for special applications.

Decorative Coatings.—For decorative purposes, plastic sheeting and cloth may be continuously coated with metals by vacuum evaporation. In the case of plastic and paper sheeting, the metal-coated product is used for the manufacture of electrical condensers. Gold leaf may also be made in this manner, by stripping the metal foil after applying to a thin surface

Other Coatings.—There are many applications for electrically conducting coatings. Piezo quartz crystals are coated with silver in order to improve frequency characteristics and stability. Conducting layers can also be applied to plastic insulated wave guides, quartz fibre suspensions for instruments, etc.

Vacuum Sputtering.—Vacuum sputtering involves coating (usually of nonconductors) by means of a gas discharge at 1 mm to 0·01 mm. The surface to be coated is placed near the Crookes dark space and a cathode formed of the material to be sputtered.

Vacuum Distillation.—At low pressures the boiling point or distillation temperature of all chemical products is materially reduced. In most commercial processes, pressures of 25 mm to 100 mm. are sufficient. This range is economically attained on a large scale with conventional steam ejectors and the fractionation of petroleum oils is one of the largest operations under such conditions

High Vacuum Distillation—Through the use of noncondensible gas pressures below 50 microns and vapour paths of low impedance, between evaporating and condensing surface, the distillation point of many high boiling products—waxes, higher alcohols, esters—is sufficiently reduced to permit purification with some fractionation without undue decomposition.

Molecular Distillation.—If the residual gas pressure is reduced to less than 10^{-3} mm Hg., a point will be reached where any further reduction has substantially no effect on the rate of distillation. If at these pressures the distance between distilling and condensing surface is small and unimpeded, so-called molecular distillation takes place. By such a technique many materials of high molecular weight may be distilled, which otherwise could be handled only with excessive decomposition, if at all

Commercially, this method has been successfully applied to the production of vitamin concentrates, by direct distillation of vitamin-bearing oils.

Electronics.—The electronics industry has long been concerned with the production of extremely low pressures. With the exception of large continuously pumped systems used with high-voltage X-ray tubes, large magnetrons, etc., high vacuum must be maintained in a closed space for long periods of time. Pressures as low as 10^{-8} mm. to 10^{-5} mm. Hg are required for many electronic devices, the lowest being necessary to prevent formation of positive ions as in cathode ray and other tubes employing high-voltage electrons Most electronic devices are now evacuated with oil diffusion pumps. In some cases (*e.g.*, receiving tubes), residual gases are absorbed with "getters" such as barium, magnesium or other reactive metals

Vacuum Impregnation.—High-vacuum techniques are commonly used as an aid to impregnation processes. Products to be treated are usually placed in a vacuum chamber and the pressure reduced to something less than 1 mm. The chamber is subsequently filled with the impregnation medium which in turn displaces the entire volume previously exhausted. This method of processing finds wide application in the electrical industry where it is a common practice to vacuum impregnate condensers, coils, transformers, cables, etc, with waxes, resins, oils or other materials of appropriate insulating characteristics.

Miscellaneous.—Industries of a wide variety employ high vacuum in one or more stages of product manufacture. In the manufacture of refrigerators it is necessary to remove all traces of water from the entire compressor system, including the small valves, pipes and fittings This is accomplished by vacuum treatment at pressures of 10 to 200 μ.

A similar procedure is employed in the manufacture of bellows-type barometers and vapour operated thermometers. In the latter case, proper calibration can be achieved only with the complete removal of both condensible and noncondensible gases prior to filling with the operating fluid. (R. S Mc)

Other applications of vacuum techniques formed the basis for such new industries as the production of citrus juice concentrates. Diffusion pumps of huge size have been employed in the metallurgical industries and the television industry. The low cost of television receivers would be impossible without the routine production of high vacuum by methods which were formerly considered a sophisticated laboratory art. The huge particle accelerators, such as the cyclotrons, the synchro-cyclotrons, the cosmotrons and the linear accelerators, all depend on diffusion pumps having speeds of tens of thousands of litres per second. (P. E K)

The manufacture of all vacuum bottles of course depends upon the maintenance of pressures below 10 μ for thermal insulation. Vacuum spectrographs permit industry to carry on spectrographic research and production control operations in the ultra-violet regions of the spectrum (R. S. Mc)

VACUUM BRAKE, a form of brake utilizing the force exerted on a piston by the pressure of the atmosphere. So long as a vacuum is maintained in the system the brake blocks are kept off the wheels.

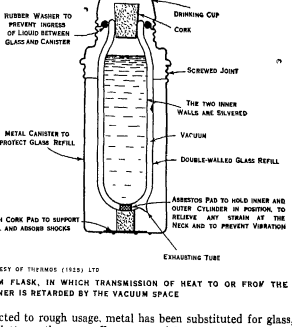
However, when air is admitted this presses against one side of the piston and applies the blocks. (*See* BRAKE; *Railway Brakes and Motor Car Brakes.*)

VACUUM CLEANER. An appliance for extracting and removing dust from fabrics, such as carpets, upholstered seats, cushions, etc, by suction, designed for the primary purpose of carrying out this operation without the necessity of displacing the articles to be cleansed from the positions which they normally occupy when in use.

It is also used to remove dust from such surfaces as those of floors, shelves, walls, etc It was so named by its inventor, H C. Booth, who made and patented the first successful appliance in the year 1901.

A vacuum cleaner consists essentially of an air suction pump, or exhauster, connected by a pipe or tube or directly to a nozzle having a slot-shaped orifice which is passed over the material being cleansed, the surrounding lip of the orifice being kept in close contact with the material.

An air filter which cleanses the air either before or after its entry into the exhauster serves at the same time as a chamber, or receptacle, for collecting the dust, which can be removed therefrom conveniently and without dispersal.



In the light portable or domestic types, this filter is often of cloth in the shape of a bag. In operation, suction from the air exhauster causes air to rush violently into the nozzle through the interstices of the fabric being cleansed and to carry away with it the imprisoned dust. (*See* also HOUSEHOLD APPLIANCES.)

(H. C. Bo , X)

VACUUM DISTILLATION: *see* DISTILLATION.

VACUUM FLASK, a glass vessel with double walls, the space between which is evacuated The only junction of the walls is at the neck of the vessel It is also known as a Dewar vessel after its inventor Sir James Dewar (*q.v.*); Thermos flask is a proprietary name applied to a form protected by metal casing.

It was invented in the first place to preserve liquefied gases (*see* LIQUEFACTION OF GASES) by preventing the transference of heat from the surroundings to the liquid. The approximate vacuum between the glass walls is practically a nonconductor of heat, and radiation is reduced to a minimum by silvering the glass. The chief path by which heat can be communicated to the interior of the inner vessel is at the junction of the walls at the vessel's neck, which is consequently made as small as possible. This thermal isolation applies equally in the opposite direction, a hot liquid remaining at a high temperature for several hours. Where the flask

BY COURTESY OF THERMOS (1925), LTD

VACUUM FLASK, IN WHICH TRANSMISSION OF HEAT TO OR FROM THE CONTAINER IS RETARDED BY THE VACUUM SPACE

is subjected to rough usage. metal has been substituted for glass, but the latter is the more efficient material.

VACUUM PUMP: *see* VACUUM

VACUUM TUBE: *see* ELECTRON TUBE.

VACZ (WAITZEN), a town of Hungary, 20 mi N. of Budapest, on the left bank of an arm of the Danube at the foot of the Cserhát mountains, where the river takes its southward course. On the hills around are large vineyards and the exportation of grapes is an important industry. There are also spirit, soap and shoe factories while the working of wool is carried on. The town is the see of a bishop and has numerous architectural remains and a museum of the Roman and mediaeval antiquities in which the district is so rich. Pop (1930), 20,960.

VADE-MECUM, a Latin phrase meaning literally "come with me" (*vade*, imperative of *vadere*, to go or come; *cum*, with; *me*, abl of *ego*, I), and used in French, Spanish and English for something that a person is in the habit of constantly taking about with him

VAGRANCY. British law against vagrancy was the outcome of more than three centuries of legislation. Sir James Stephen's *History of the Criminal Law*, dealing with vagrancy as a criminal offense, states that "when serfdom was breaking down and when the statutes of labourers provided what might be regarded as a kind of substitute for it, provisions as to vagrancy were practically punishments for desertion. The labourer's wages were fixed, his place of residence was fixed, he must work where he happened to be If he went elsewhere, he must be taken and sent back By degrees the order of ideas which this view of the subject represented died away. The vagrant came to be regarded rather as a probable criminal than as a runaway slave"

The act of 1495 instructed local authorities to search for all "vagaboundes, idell and suspecte persones, lyvyng suspeciously" and put them in the stocks for three days, giving them bread and water only, and then turn them out of the town. In 1530, owing to the increase of vagrancy followed by crime and disorder, whipping was allowed as an alternative to the stocks In 1535 an even severer punishment for the sturdy vagabond was enacted If brought a second time before a justice of the peace he might be marked by having the upper part of his right ear cut off and after this if convicted of wandering, loitering and idleness might be adjudged a felon and suffer death. Other drastic acts followed until 1597 when fortune tellers, tinkers, pedlars, jugglers, etc., were all treated as rogues and vagabonds and even players except such as "belonged to any baron of this realm or any other honourable person of greater degree" This law remained in force with amendments until orders in council in 1603 and 1662 empowered the authorities to transport sturdy beggars and idle and disorderly persons to English plantations beyond the seas. Branding ceased to be legal in 1713. In 1821 a select committee of the house of commons dealing with the system of "passing" vagrants to their place of settlement recommended that the existing system should be abolished and long periods of imprisonment given instead.

As a result of the report, the existing legislation was in 1822 repealed "en bloc" and the new act to remain in force till 1824 reduced the powers of magistrates with regard to vagrants and also reduced the maximum term of detention from seven years' transportation to two years' imprisonment. Finally the Vagrancy act of 1824 repealed all former statutes and "vagrancy offenders were liable to punishment either as "idle and disorderly persons" or as "rogues and vagabonds" or as "incorrigible rogues" Since 1824 legislation and regulations have both been based on reports made by the poor law commission, and under the poor law as reformed in 1834 it became the duty of the guardians to provide relief for destitute persons and to use a test to make sure that relief given from the public funds was not abused. When workhouses were established vagrants applied for admission to them and in 1837 the poor law commissioners expressed the opinion that it was the intention of the act of 1834 that all cases of destitution should be relieved irrespective of the fact that the applicant might belong to a distant parish.

There have been many acts since that time, such for example, as the act of 1842 proscribing a task of work in return for food and lodging and the Poor Law act of 1844 authorizing the formation of districts in London and other large towns for the provision of temporary relief. In 1848 when the poor law board took the place of the poor law commissioners the whole question of vagrancy was reported on by the inspectors to the new board and a minute of the poor law board urged uniformity in action, the refusal of relief to able-bodied men not actually destitute, and the employment of police officers as assistant relieving officers for vagrants Under the act of 1864 every London union was required to provide casual wards.

The "Casual."—Nearly all subsequent legislation deals with the treatment of the casual pauper and the regulations that should be enforced especially when the applicant for admission to a casual ward was an able-bodied man. A general order dated Dec. 18, 1882, prescribed the rules and regulations to be observed and pauper vagrancy decreased for two or three years, but increased again from 1885 to 1895. The number of vagrants in casual wards on Jan 1, 1905, was 9,768. There followed the appointment of the departmental committee on vagrancy in 1906. The recommendations of the committee on vagrancy, of which the Rt Hon J L. Wharton was chairman, were of a varied character, some of which could not be carried into effect without legislation. For example, it was suggested that the control of casual wards and the local relief of vagrants should be transferred to the police authority with a view to securing uniform treatment throughout the country By the 1930s it was often necessary for tramps to apply for tickets at police stations before they could sleep in the casual ward, although the police had no final control. Another recommendation was that of a detention colony and an indeterminate sentence, a detention colony, for example, such as Borstal for boys and the place of detention for an indefinite period instead of prison for a short term. The committee recommended that habitual vagrants should be sent to certified labour colonies for detention for not less than six months or more than three years. The third recommendation, which passed into law, was that of the establishment of labour exchanges the value of which for the unemployed tramp was that information could be obtained at a labour exchange as to where employment was likely to be found. The difficulty however was that if a man was compelled without money to tramp the country he could not stay long enough in one place to enable him to find employment. A considerable advance was made in the direction of forming vagrancy committees for counties or larger areas, the object being to secure uniform treatment of tramps, to find work for those willing to work and to deal with the difficulty of women and children on the road A number of counties also adopted the suggestion of a way-ticket system. By a statutory order of Sept. 23, 1914, the

supply of a midday meal for paupers discharged from the casual ward was legalized The way-ticket system was by no means universally adopted and has not been a success.

The Metropolitan Asylums board by unifying the London tramp wards introduced uniformity in administration and generally speaking the London casual wards are clean and well-kept. As a result of the report of the casual wards committee of the Metropolitan Asylums board many helpable cases were dealt with separately, the idea being to enable those who were really desirous of work to stay in a ward which was treated as a hostel A stay of a week or a fortnight often meant that the man was able to find employment. The implication is that the casual ward with its one or two nights detention did not assist the man to find employment, but that given a longer time a considerable number of men could be assisted to find work

Remedies.—The labour exchange should theoretically enable an unemployed man, likely to become a vagrant, to be transferred to some place where work is more abundant, but the labour exchanges are in many cases overworked and have a mass of local unemployment to deal with, most of it stagnant labour. If the occupants of casual wards could be given a chance there is no doubt that a percentage, small perhaps, but probably not less than 10% would be willing to work if suitable employment could be found. To obtain this fluidity of labour some arrangement is required to enable the man to travel from place to place and this entails the expenditure of money. He also requires when he arrives at a new town some decent accommodation other than the casual ward. Vagrancy reform must be based upon effective individual dealing and proper classification since the vagrant may be either a genuine unemployed man, an ex-serviceman, an old and infirm person, a young boy, a married man with a wife and children, or an habitual vagrant.

Like all social problems vagrancy cannot be isolated from other important questions such as housing, poor-law reform and unemployment. It is a symptom of a deeply rooted social evil which must be remedied by dealing with the other problems which lie at the root of the trouble (*See* also POOR LAW; CASUAL WARD; FARM COLONY; UNEMPLOYMENT.)

BIBLIOGRAPHY.—For a history of vagrancy *see* C J Ribton-Turner, *History of Vagrants and Vagrancy* (1887), *see* also *Reports, Evidence and Appendices of Departmental Committee on Vagrancy* (1906), a most valuable publication, as well as *The Vagrancy Problem* (1910), by W. H. Dawson, who was a witness before the committee, and whose work quoted is full of first-hand information Two Board of Trade *Reports* on "Agencies and Methods for Dealing with the Unemployed" (1893 and 1904) will be found useful, as will also Rev. W. Carlile and V. W. Carlile's *The Continental Outcast* (1906), Mary Higgs, *Down and Out. Studies in the Problems of Vagrancy*; "Royal Commission on the Poor Law," appendix to *Reports on Visit to Labour Colonies*, vol. xxxii. (1919), *Ministry of Reconstruction Report on Transference of Function of Poor Law* (1918). (P. A.; X.)

The United States.—Vagrancy laws in the United States began to appear after the economic depression of 1873 (New Jersey, 1876; Delaware, 1879, New York, 1884) and after the even greater depression of 1893.* Owing to the unique nature of the problem in the United States these laws attempted to differentiate between the vagrant or loafer, about town, and the tramp who roved "about from place to place." Both were "idle persons without visible means of support" only the tramp was more of a romantic adventurer. In other connections he is known as a migratory worker or hobo. He was a conspicuous figure in the building of railroads, prospecting and clearing the land during the strenuous drive against the frontier. With the passing of the frontier he continued in his role as tramp and migratory worker, but he now functions in only the seasonal industries and transient occupations. The migratory worker, because of his facility in using the railroads, is more mobile than any type of vagrant so far developed In the main he is self-sustaining, and when he is not, his problem is as much a matter of unemployment as of vagrancy. His labour market is elusive; harvesting, sheep shearing, lumbering, ice cutting and the like; and his fortunes are no less elusive. However legitimate his function may be in the country's industrial set-up, he still leads a precarious, hand-to-mouth existence, moving from job to job, from state to state at the beck and call of his opportunities, and not infrequently of his moods Most of his life the hobo lives in the open, especially in summer when if he is not at work or travelling to the next job he is basking in the "jungles," his roadside camps. In winter when work is scarce he is frequently forced into some city for food and shelter, and it is then that he gets his rating as a vagrant.

The life of the hobo is divided between train riding, the job, the "jungle" and the "main stem," or the street of the homeless found in most cities In most of his contacts he is relatively isolated from women, so hobo life becomes a man's game A population recruiting its new membership from young men and boys, it has little of the culture traits, jargon and sign language that some observers attribute to vagrants of the old world Since so many boys and young men are attracted into the class and since the promise of adventure generally proves a delusion there is naturally considerable unrest, which may explain the zeal with which hobos often turned to syndicalism Manifestations of unrest, songs of protest, and rapid movement, especially of younger hobos, about the country, all appeared with the passing of the frontier and the swing of the country from a rural to an industrial, city-building civilization The hobo of the old school who lived his life in the open, tramping and working by turns, and carrying his bed wherever he went, began to vanish Whereas the old-type hobo used to avoid the city, the modern species of the undomesticated American is essentially urban, and only when necessity forces him does he venture into the country.

Most attempts in the large cities to cope with the problem of vagrancy were partial and palliative. Small cities at one time opened their jails for winter lodging but that practically ceased after World War I Other cities drove tramps out of town; and others established wood yards to give the work test Numerous cities have municipal lodging houses and in addition private agencies, such as the Salvation Army, maintain industrial shops and transient hotels. In every large city during hard times, and often the year through, bread lines and soup kitchens may be found None of these efforts meets the problem in any comprehensive fashion

Jacob S Coxey who led "Coxey's army" of unemployed to Washington, D C, in 1894 demanded that the government should put them to work building roads. That proposal was often made but only with transient success. One of the earliest instances was in New York city in 1808 during a riot of unemployed sailors.

(N. A., X.)

VAI, a people of the Mandinga group, on the Guinea coast in Liberia and Sierra Leone, who are remarkable for their use of a syllabic script consisting of more than 150 signs invented in the first half of the 19th century by Momolu Doalu Bukere.

See Migeod, *The Languages of West Africa* (1911)

VAIDA-VOEVOD, ALEXANDRE (1871–1950), Rumanian statesman, was born at Olpret, Transylvania, in 1871. He studied medicine in Vienna and practised for many years at Karlsbad (Karlovy Vary). At the age of 28 he joined the National Rumanian party of Transylvania and from 1906–18 sat in the Hungarian parliament at Budapest, where he waged a permanent fight in defense of the Rumanians in Transylvania. On the collapse of the Central Powers in the autumn of 1918, Vaida-Voevod was instructed by the newly formed "Rumanian National committee," to voice their claims in the Hungarian parliament Invoking the right of self-determination he denied the right of the Hungarian government to speak in the name of the Rumanians of Transylvania and claimed that the latter should have their own representative at the peace conference Soon after, the Rumanian National committee took administrative control of Transylvania and delegated Vaida-Voevod to represent the Rumanians of Transylvania and the Banat at the peace conference in Paris.

In 1919 Vaida-Voevod was appointed prime minister and minister for foreign affairs of Rumania and in the latter capacity went to Paris and London early in the following year to negotiate with the French and British governments the recognition of the union of Bessarabia with Rumania. This he succeeded in doing in March 1920 when the rights of Rumania over Bessarabia were recognized by the Supreme Economic council, and afterward ratified by the Treaty of London (Oct. 28, 1920). Vaida-Voevod resigned in the same year and afterward sat in parliament as one of the leaders of the National Rumanian party, from which he later resigned. He was prime minister again from Aug. to Oct.

1932, and from Jan to Nov. 1933. He died March 19, 1950.

VAIL, THEODORE NEWTON (1845–1920), U S capitalist, was born in Carroll county, O, on July 16, 1845 He became interested in telegraphy, and in 1868 he became station agent and telegraph operator on the Union Pacific Then he was appointed clerk in the railway mail service, and in 1873 was made assistant superintendent of railway mail service, rising in 1875 to general superintendent In 1878 he was made general manager of the American Bell Telephone company. In 1885 he resigned and was elected president of the newly organized American Telephone and Telegraph company, which in 1900 acquired the American Bell Telephone company. In 1887, because of ill-health, Vail retired. In 1896 he installed an electric railway system in Buenos Aires, and later introduced telephone systems in South American cities.

In 1907 he was again induced to accept the presidency of the American Telephone and Telegraph Company. When this company in 1910 bought control of the Western Union Telegraph company Vail was made president of the latter also, and introduced many changes, including "night letters" at reduced rates. When in 1914, as the result of a threatened suit by the government, the Western Union was again segregated Vail remained president of his old company. After the taking over of the wires in Aug. 1918 by the government as a war measure, he was appointed adviser by the postmaster-general. When the wires were returned in 1919 to private ownership he was elected chairman of the board of directors of the American Telephone and Telegraph company. He died in Baltimore, Md, on April 16, 1920.

See A B Paine, *In One Man's Life* (1921).

VAILLANT, EDOUARD MARIE (1840–1915), French politician, was born in Vierzon, Cher, on Jan. 28, 1840 He studied science, residing in Heidelberg, Tubingen and Vienna. On his return to Paris he took part in the republic and socialist battle against the Second Empire, becoming a disciple and friend of Louis Blanqui On March 18, 1871, he took part in the Commune insurrection, and, on the 26th, was elected a member of the Commune. He was a delegate on the executive commission, and his work for public instruction displays his revolutionary audacity and his scientific knowledge.

After the defeat of the Commune he fled to England and became associated with Karl Marx. But, after having been a member of the general committee of the First International, after having participated in 1872 in the congress at The Hague, he induced his friends to abandon this association because it seemed to him to be insufficiently revolutionary. He founded "The Revolutionary Commune" which published the manifesto in which these disciples of Blanqui declared themselves to be atheists, republicans, communists, revolutionaries and partisans of class conflict.

Condemned to death by the war council in 1872, Vaillant only returned to France in 1880 under amnesty. He was a founder of the Socialist Revolutionary party, and in 1884, he became a municipal councillor of Paris, becoming deputy in 1893. Under his direction, the Blanquist party made itself noticeable among the other socialist parties. In Boulangisme (1889), he separated from other blanquists, who, through nationalism, were inclined to accept a plebiscitary dictator.

In 1899, and again in 1905, Vaillant made himself the apostle of socialist unity in France When in 1905, all the socialist parties united, he became a very close friend of Auguste Jaurès, and secured with him the majority in all socialist congresses until 1914. He advocated the eight-hour day, security and hygiene for workers, remedies against stoppage of work, and a struggle against war.

In Aug. 1914 he considered that France was attacked and that it was the duty of the socialists to defend it, as in 1870 and 1871. He resumed the formulas of Blanquist socialism and declared himself unreservedly in favour of national defense.

VAIRAGI: *see* RAMATS.

VAISHNAVITES (Bengal). Chaitanya, the founder of the great Vaishnava sect of Bengal, was the son of a high-caste Brahman of Nadiya, the famous Bengal seat of Sanskrit learning, where he was born in 1485, two years after the birth of Martin Luther, the German reformer. Having married in due time, and a second time after the death of his first wife, he lived as a householder (*grihastha*) till the age of 24, when he renounced his family ties and set out as a religious mendicant (*vairagin*), visiting during the next six years the principal places of pilgrimage in northern India, and preaching with remarkable success his doctrine of Bhakti, or passionate devotion to Krishna, as the supreme deity.

He subsequently made over to his principal disciples the task of consolidating his community, and passed the last 12 years of his life at Puri in Orissa, the great centre of the worship of Vishnu as Jagannatha, or "lord of the world," which he remodelled in accordance with his doctrine, causing the mystic songs of Jayadeva to be recited before the images in the morning and evening as part of the daily service, and seeking to humanize divine adoration by bringing it into accord with the experience of human love. To this end, music, dancing, singing parties (*sankirtan*), theatricals—in short anything calculated to produce the desired impression—would prove welcome to him.

His doctrine of Bhakti distinguishes five grades of devotional feeling in the Bhaktas, or faithful adherents: viz., (*santi*) calm contemplation of the deity; (*dasya*) active servitude; (*sakhya*) friendship or personal regard; (*vatsalya*) tender affection as between parents and children; (*madhurya*) love or passionate attachment, like that which the Gopis felt for Krishna. Chaitanya promoted the celebration on an imposing scale of the great Puri festival of the Rathayatra, or car procession, in the month of Ashadha, when, amidst multitudes of pilgrims, the image of Krishna, together with those of his brother Balarama and his sister Subhadra, is drawn along, in a huge car, by the devotees. This festival was, and is, attended by people from all parts of India, without distinction of caste or sex. All classes, even Mohammedans, were admitted by Chaitanya as members of his sect. The ordinary form of worship is very simple, consisting mainly of the constant repetition of names of Krishna, or Krishna and Radha, which of itself is considered sufficient to ensure future bliss. The partaking of flesh food and spirituous liquor is strictly prohibited. By the followers of this sect, also, an extravagant degree of reverence is habitually paid to their *gurus* or spiritual heads Indeed, Chaitanya himself, as well as his immediate disciples, have come to be regarded as complete or partial incarnations of the deity to whom adoration is due, as to Krishna himself; and their modern successors, the Gosains, share to the fullest extent in the devout attentions of the worshippers. Chaitanya's movement was directed against the vile practices of the Saktas (*see* SAKTISM) then very prevalent in Bengal, but his own doctrine of divine, though all too human, love was by no means free from corruptive tendencies. While in Chaitanya's creed, Krishna, in his relations to Radha, remains at least theoretically the chief partner, an almost inevitable step was taken by some minor sects in attaching the greater importance to the female element, and in this way making Krishna's love for his mistress the guiding sentiment.

VAISON-LA-ROMAINE, a town of southeastern France, in the department of Vaucluse, 26 mi.•N.N.E. of Avignon by road. Pop. (1946) 2,188. Vaison, under the name of *Vasio*, was one of the principal towns of the *Vocontii*; the number of Roman finds, including a fine statue of an athlete (the Diadumenos) in the British Museum, proves its importance in Roman times. The bishopric established in the 3rd century was suppressed in 1791 The temporal power of the bishops passed in the 12th century to the counts of Toulouse. Subsequently Vaison came, together with the rest of Comtat-Venaissin, under the power of the popes. The Ouvèze, a tributary of the Rhône, divides Vaison into two quarters—the Roman and early mediaeval town on the right bank and the mediaeval town on the left bank.

VALAIS, a canton of south Switzerland. The region is the old *Vallis Poenina* (Upper Rhône valley). The former spelling, Vallais, was officially replaced in the early 19th century by Valais.

The modern canton includes the entire basin above St. Maurice, but below this point it consists of the western part only; its lower limits are in the Lake of Geneva. The total area is 2,020.7 sq.mi. (exceeded only by the Grisons and Berne), of which, however, only 55.9% is reckoned as productive; forests cover 282.6 sq mi.

and vineyards 12.2 sq.mi. Its unproductive area includes the most considerable stretch of glaciers in Switzerland (*c* 375 sq mi.), together with about 5 sq mi. of lakes. Poor as the canton is, it would be poorer were it not for its excellent wines—the area under vineyards is second only to Vaud (*q v*) and is increasing—and for its well-organized tourist traffic. Hotels have been built in nearly every tributary glen, and on the majority of the high pastures. The striking beauty of the scenery of its high glens, and the accessibility (*see* below) of the most characteristic features, have made the canton unusually popular, chiefly with summer visitors. The Upper Rhône occupies a northeast to southwest gorgelike trench from Gletsch to Brig, below this the valley widens and runs east to west to Leuk; onward it resumes its original course, ever widening until Martigny is reached, where the remarkably sharp bend carries the feature to the northwest; between St. Maurice and the lake is the only low land in the canton The lowest commune is St. Gingolph (1,266 ft. alt.). The loftiest point is the Dufourspitze summit (15,200 ft) of Monte Rosa, but the highest mountain wholly within the canton is the Dom (14,942 ft.). (*See* SWITZERLAND: *Physical Geography.*)

The chief railway line (about 75 mi.) through the canton is from St. Gingolph, on the Lake of Geneva, to Brig, at the north mouth of the Simplon tunnel (1895–1905—12½ mi. long); from St. Maurice onward it forms part of the main through line from Lausanne toward Milan. There are also several mountain railways; *e g*, from Visp up to Zermatt (thence a branch up to the Gornergrat), from Vernayaz (near Martigny) past Salvan toward Chamonix, and from Leuk to Leukerbad, near the Gemmi pass and noted for its mineral springs A new tunnel (1906–12) beneath the Lötschen pass, connects Kandersteg, in the Bernese Oberland, with Brig, thus opening up a new direct route from Paris to Italy, via Berne. The lofty alpine barriers of Valais are, as a rule, accessible only by footpaths or mule paths, but there are excellent roads over the Great St. Bernard pass (8,094 ft.) and the Simplon pass (6,591 ft.) to Italy, while at the head of the Rhône valley other excellently engineered roads give access to Uri over the Furka pass (7,992 ft.) and to Berne over the Grimsel pass (7,100 ft)

In general, the boundaries of the canton run along the summit ridges of the surrounding mountains, but from an early date it has held a valuable part of the southern slope of the Simplon pass to below Gondo, as well as the rich Alpine pastures on the northern slopes between the Gemmi pass (7,641 ft) and Schwarzenbach.

The total population thus the census of 1910 was 159,178; in 1930 it was 136,394, of whom 88,498 were French-speaking, 44,275 were German-speaking and 3,269 were Italian-speaking. The Italians decreased in number during the 20th century. The linguistic frontier has shown much oscillation; at present the inhabitants above Leuk generally speak a dialect of German, while below Leuk a Savoyard patois (French dialect) is the prevailing tongue In general, the history of Valais (from 1810 to 1814 the French department of the Simplon) is a struggle between French and German elements. It is one of the last three admissions to the confederation. In 1930 there were 130,801 Catholics, 4,662 Protestants and 48 Jews

The canton forms the 4th-century diocese of Sion (created *c.* 580) and has St. Théodule as its patron saint. Since 1513 its bishop has had no superior except the pope Valais contains the three famous religious houses (all now held by Austin canons) of St. Maurice, of the Great St. Bernard, and of the Simplon. The abbey of St. Maurice (4th century and the oldest Christian foundation among the Alps) has, since 1128, belonged to the Augustinians. Since 1840 its abbot has borne the title of bishop of Bethlehem *in partibus.*

Good wines, especially muscat and *vin du glacier,* are produced in the canton, but the chief activity of the main valley below Brig is agriculture, rendered rather precarious in former days by extensive Rhône inundations. In the higher valleys the inhabitants are employed in pastoral occupations. The number of mountain pastures is greater, and they are better stocked in the more congenial Lower Valais than in Upper Valais (the line of division passing near Leuk). The capital is Sion (pop. 10,904). The canton has no large towns. The average density of the population in 1950, 79 per sq.mi , was but little above that of Uri (*q v.*) Of the larger settlements, Monthey (5,608)—near St. Maurice—with an electric railway up the Val d'Illiez to Champéry, and Brig (3,854) are the most important. Naters, near the latter town, has a prosperous colony of Italian workmen.

Valais is divided into 13 administrative districts, which comprise 170 communes. The cantonal constitution was entirely remodelled in 1907. The legislature (*grand conseil*) is composed of 119 members elected by the people in the proportion of one for every 1,100 Swiss residents. The executive (*conseil d'état*) is composed of five members. Both councils hold office for four years The obligatory referendum prevails for all laws and financial resolutions passed by the *grand conseil,* while 4,000 electors (6,000 in the case of a revision of the cantonal constitution) have the right of initiative as to legislative projects; the latter initiative dates back to 1848. The canton provides two members of the federal *Standerat* and six members of the federal *Nationalrat,* elected by a popular vote. The principles of proportional representation are employed in communal elections.

History.—The Vallis Poenina was won by the Romans after a great fight at Octodurus (Martigny) in 57 B C , and was so thoroughly Romanized that the Celtic aboriginal inhabitants and the Teutonic Burgundian invaders (5th century) became Romance-speaking peoples. Valais formed part of the kingdom of Transjurane Burgundy (888), which fell to the empire in 1032, and later of the duchy of Burgundia Minor, which was held from the emperors by the house of Zähringen (extinct 1218). In 999 Rudolph III of Burgundy gave all temporal rights and privileges to the bishop of Sion, who was later styled "praefect and count of the Valais." About the middle of the 13th century independent communities or tithings (*dizains* or *Zehnten*) were growing up, these, though seven in number, taking their name most probably from a very ancient division of the bishop's manors for administrative and judicial purposes. In the same century the upper part of the valley was colonized by Germans from Hasli (Bern), who Teutonized it, though many Romance local names still remain. In 1354 the liberties of several of the seven tithings (Sion, Sierre, Leuk, Raron, Visp, Brieg and Conches) were confirmed by the emperor Charles IV. A little later the influence of Savoy became predominant, and the count secured to his family the bishopric of Sion, of which he was already the suzerain. His progress was resisted by the tithings, which in 1375–76 crushed the power of the house of La Tour-Châtillon, and in 1388 utterly defeated the forces of the bishop, the count and the nobles at Visp, this being a victory of the Teutonic over the Romance element in the land

From 1384 the Morge stream (a little below Sion) was recognized as the boundary between Savoyard or Lower Valais and episcopal or Upper Valais. In 1416–17 the *Zehnten* of the upper valley made an alliance with Lucerne, Uri and Unterwalden, with a view partly to the conquest of the Val d'Ossola, which was finally lost in 1422, and partly to the successful crushing of the power of the lords of Raron (1420) By the election of Walther von Supersax of Conches as bishop in 1457 the Teutonic element finally won the supremacy. On the outbreak of the Burgundian War, the bishop of Sion and the tithings made a treaty with Bern In November of the same year (1475) they seized all Savoyard or Lower Valais up to Martigny, and in 1476 (March), after the victory of Grandson, won St. Maurice, Evian, Thonon and Monthey. The last three districts were given up in 1477, but won again in 1536, though finally by the treaty of Thonon in 1569 Monthey, Val d'Illiez and Bouveret alone were permanently annexed to the Valais, these conquests being maintained with the help of their old allies, Uri, Schwyz and Unterwalden. These districts (or Lower Valais) were ruled as subject lands by the bishop and tithings of Upper Valais In 1790–91 Lower Valais rose in revolt, but it was not finally freed till 1798, when the whole of Valais became one of the cantons of the Helvetic republic. Such prolonged resistance, however, was offered to French rule that in 1802 Bonaparte declared Valais an independent state under the name of the "Rhodanic Republic" In 1810, for strate-

gic reasons, he incorporated it with France as the "department of the Simplon," and it was not freed till the Austrians came in 1813. In 1815 a local assembly was created, in which each of the seven tithings of Upper, and each of the six of Lower Valais elected four members, the bishop being given four votes. This constitution was approved by the federal Swiss diet, and the Valais was received as a full member of the Swiss confederation By the constitution of 1839, the local assembly was to be elected according to population (1 member for every 1,000 inhabitants), and the bishop was given a seat instead of his four votes, while the clergy elected one deputy. By the 1844 constitution the clergy elected a second deputy In 1844 there was civil war, and the Valais became a member of the Sonderbund. It was the last canton to submit in the Sonderbund War (1847). By the constitution of 1848 all ecclesiastical exemptions from taxation were swept away, and the bishop lost his seat in the assembly. New constitutions were framed in 1852, 1875 and 1907. (*See* SWITZERLAND. *History*)

VALDEMAR I, king of Denmark (1131–1182), the son of Canute Lavard and the Russian princess Ingeborg, was born a week after his father's murder, and was brought up in the religious and relatively enlightened household of Asser Rig, whose sons Absalon and Esbjorn Snare, or "the Swift," were his playmates. On the death of King Eric Lam in 1147 Valdemar came forward as one of the three pretenders to the Danish crown, Jutland falling to his portion (compact of Roskilde [1157]). Narrowly escaping assassination at a banquet a few days later, at the hands of his rival, King Sweyn III, he succeeded only with the utmost difficulty in escaping to Jutland, but on Oct. 23 utterly routed Sweyn at the great battle of Grathe Heath, near Viborg, Sweyn perishing in his flight from the field.

Valdemar had no longer a competitor He was the sole male survivor of the ancient royal line; his valour and ability were universally recognized, and in Absalon, elected bishop of Roskilde in 1158, he possessed a minister of equal genius and patriotism. The first efforts of the new monarch were directed against the Wendish pirates who infested the Baltic and made not merely the political but even the commercial development of the Danish state impossible. What the Northmen were to the western powers in the 8th and 9th centuries the Wends were to the Scandinavian lands in the 11th and 12th centuries. At the beginning of the reign of Valdemar the whole of the Danish eastern coast lay wasted and depopulated. Arkona, the chief sanctuary, and Garz, the political capital of the Wends, in the island of Rügen, were captured in 1169 by a great expedition under the command of Valdemar and Absalon; the hideous colossal idol of Rügievit was chopped into firewood for the Danish caldrons, and the Wends were christened at the point of the sword.

This triumph was only obtained, however, after a fierce struggle of ten years, in which the Danes were much hampered by the uncertain and selfish co-operation of their German allies, chief among whom was Henry the Lion, duke of Saxony and Bavaria, who appropriated the lion's share of the spoil. For at the beginning of his reign Valdemar leaned largely upon the Germans and even went the length, against the advice of Absalon, of acknowledging the overlordship of the emperor Frederick Barbarossa at the diet of Dôle, 1162. Very different was Valdemar's second conference with Barbarossa, on the banks of the Eider in 1182, when the two monarchs met as equals in the presence of their respective armies and a double marriage was arranged between two of Valdemar's daughters and two of the emperor's sons.

The only serious domestic trouble during Valdemar's reign was the rebellion of the Scanian provinces, which objected to the establishment of a strong monarchy inimical to local pretensions and disturbances, and especially to the heavy taxes and tithes necessary to support the new reign of law and order. The rising was ultimately suppressed by Absalon at the battle of Dysiaa, 1181 In the following year King Valdemar died.

BIBLIOGRAPHY.—*Danmarks Riges Historie*, vol. I, pp. 570–670 (Copenhagen, 1897–1905); Saxo, *Gesta Danorum*, books 10–16 (Strasbourg, 1886); L. Gressebrecht, *Wendische Geschichte aus den Jahren 780–1182* (Leipzig, 1843); and article DENMARK: *History*. (R N. B.; X.)

VALDEMAR II, king of Denmark (1170–1241), was the second son of Valdemar I and brother of Canute VI, whom he succeeded on Nov. 12, 1202. Already during his brother's lifetime, as duke of Schleswig, Valdemar had successfully defended Denmark against German aggression. In 1201 he assumed the offensive, conquered Holstein, together with Hamburg, and compelled Count Henry of Schwerin to acknowledge the overlordship of the Danish crown. Immediately after his coronation, he hastened to his newly won territories, and was acknowledged lord of Northalbingia (the district lying between the Eider and the Elbe) at Lubeck, Otto IV, then in difficulties, voluntarily relinquishing all German territory north of the Elbe to Valdemar, who in return recognized Otto as German emperor. Thus the three bishoprics of Lübeck, Ratzeburg and Schwerin, which hitherto had been fief of the *Reich*, now passed under Danish suzerainty. In 1208, when the emperor Otto felt more secure upon his unstable throne, he would have attempted the recovery of the lost German territory but for the interposition of Pope Innocent III, who threatened to excommunicate any German prince who should attack Valdemar, the equally pious and astute Danish king having undertaken, at the bidding of the holy see, to lead a crusade against the heathen Estonians. Valdemar's position was further strengthened by the accession of Frederick II, who formally renounced all the German lands north of the Elbe and Elde, as well as the Wendish lands on the Baltic, in favour of Valdemar.

Valdemar henceforth turned to the extension of the Danish empire over the eastern Baltic shores. There, however, he had already been forestalled by German colonists established in Gotland and at Riga In 1206 Valdemar, urged by Archbishop Anders Sunesön, had occupied the Isle of Oesel on the Estonian coast. In 1210 Valdemar led a second expedition eastward, this time directed against heathen Prussia and Samland, the chief result of which was the subjection of Mestwin, duke of Pomerania, the leading chieftain in those parts

In 1218 the German Bishop Albert of Riga was driven to appeal for assistance to King Valdemar. Valdemar cheerfully undertook a new crusade "for the honour of the Blessed Virgin and the remission of my own sins." In 1218 he set sail for Estonia with one of the largest fleets ever seen in northern waters, including a Wendish contingent led by Prince Vitslav. Landing at Lyndantse (the modern Reval) in north Estonia, Valdemar at once received the submission of the inhabitants, but three days later was treacherously attacked in his camp and only saved from utter destruction by his own personal valour and the descent from heaven, at the critical moment, of a red banner with a white cross on it, the Dannebrog (Danes' Cloth), heard of for the first time, and which henceforth was to precede the Danish armies to victory till its capture by the Ditmarshers, three hundred years later. This victory was followed by the foundation of Reval and the occupation of Harrien and Wirland, the northern districts of Estonia, by the Danes

King Valdemar II was then, after the king of England, the most powerful potentate in the north of Europe. The south-western Baltic was a Danish sea, and Danish territory extended from the Elbe to Lake Peipus. But this scattered and heterogeneous empire required a large standing army and a strong central government to hold it together. It is doubtful whether even the genius of Valdemar would have proved equal to such a stupendous task. He never had the opportunity of attempting it. In May 1223 he was seized at midnight in his tent on the isle of Lyö, where he had gone to hunt, by his vassal and guest Count Henry of Schwerin, and conveyed with his son and many other valuable hostages to the inaccessible castle of Dannenberg-on-Elbe. In this dungeon he languished for two and a half years, and despite all the efforts of Pope Honorius III on his behalf, he was ultimately forced to pay a heavy ransom and surrender Northalbingia and all his Wendish conquests except Rugen.

On his release he tried to retrieve his position by force, but was defeated at Bornhöved (July 22, 1227), which deserves a place among the decisive battles of history, for it destroyed at once and for ever the Danish dominion of the Baltic and estab-

lished the independence of Lübeck, to the immense detriment in the future of all the Scandinavian states. On the other hand Valdemar, by prudent diplomacy, contrived to retain the greater portion of Danish Estonia (compact of Stensby, 1238). With rare resignation Valdemar devoted the remainder of his life to the great work of domestic reform. His noblest achievement in this respect is the codification of the Danish laws known as the *Jydske Lov* (Jutland Code), which he lived to see completed a few days before his death at Vordingborg on March 21, 1241. Valdemar was twice married, his first consort being Dragomir (Dagmar) of Bohemia, his second Berengaria of Portugal. All his four sons, Valdemar, Eric, Abel and Christopher, became kings of Denmark

See *Danmarks Riges Historie*, vol. i, pp. 736–849 (Copenhagen, 1897–1905) (R. N. B.; X.)

VALDEMAR IV, king of Denmark (*c.* 1320–1375), was the youngest son of Christopher II of Denmark. Valdemar was brought up at the court of the German emperor Louis of Bavaria during those miserable years when Denmark was partitioned among Holstein counts and German *Ritter*, while Scania, the breadbasket of the monarchy, sought deliverance from anarchy under the protection of Magnus of Sweden. Even the Hansa towns, the hereditary enemies of Denmark, regarded the situation with disquietude. "One would gladly have seen a single king in Denmark if only for peace sake," says the contemporary Lübeck chronicle, "for peace was not to be had either at sea or on land." The assassination at Randers of the detested Holstein tyrant Count Gerhard III (1340), who for nine years had held Jutland and Funen and dominated the rest of Denmark, first opened Valdemar's way to the throne, and on midsummer day 1340 he was elected king at a *Landsting* held at Viborg, after consenting to espouse Helveg, the sister of his most important confederate, Valdemar, duke of Schleswig

Valdemar could not have been more than 20 when he became the nominal king of Denmark, though, as a matter of fact, his territory was limited to the northernmost county of Jutland. His precocious maturity is strikingly evident from the first. An energy which never slackened, a doggedness which no adversity could crush, a fiery ambition coupled with the coolest calculation, and a diplomatic unscrupulousness which looked always to the end and never to the means, these were the salient qualities of the reconstructor of the dismembered Danish state First Valdemar aimed at the recovery of Zealand, which was actually partitioned among a score of Holstein mortgagees who ruled their portions despotically from their strong castles and sucked the people dry. The oppressed clergy and peasantry regarded Valdemar as their natural deliverer; but the work of redemption proved painfully slow

In Nov 1343 Valdemar obtained the town and castle of Copenhagen from King Magnus Smek of Sweden by reconfirming in still more stringent terms the previous surrender of the rich Scanian provinces, and by the end of the following year he had recovered the whole of North Zealand In 1347 the remainder of Zealand was redeemed, and the southern islands, Laaland, Falster and Mon, also fell into the king's hands. By this time, too, the whole of Jutland (except the province of Ribe) had fallen to him, county by county, as their respective holders were paid off In 1349 at the *Landsting* of Ringsted, Valdemar proudly rendered an account of his stewardship to the estates of Zealand, and the bishop of Roskilde congratulated him on having so miraculously delivered his people from foreign thraldom In Aug. 1346, he prudently rid himself of the distant and useless province of Estonia by selling it very advantageously.

In north German politics Valdemar interfered to protect his brother-in-law the Margrave Louis of Brandenburg against the lords of Mecklenburg and the dukes of Pomerania, with such success that the emperor Charles IV, at the conference of Bautzen, was reconciled to the Brandenburger and allowed Valdemar an annual charge of 16,000 silver marks on the city of Lubeck (1349). Some years later Valdemar even contemplated a descent on England in alliance with the French king John, but the chronic state of rebellion in western Denmark, fomented by the discontented Jutish magnates, lasted with short intervals from 1350 to 1360 and compelled Valdemar to renounce this fantastic design. But he proved more than a match for his domestic rebels, especially after his great victory at Brobjaerg in Funen (1357). Finally, the compact of Kalundborg restored peace to the kingdom.

Valdemar now turned his eyes to the "kingdom of Scania" Valdemar had indeed pledged it solemnly and irrevocably to King Magnus of Sweden, who had held it for 20 years; but profiting by the difficulties of Magnus with his Norwegian subjects, after skilfully securing his own position by negotiations with Albert of Mecklenburg and the Hanseatic league, Valdemar suddenly and irresistibly invaded Scania, and by the end of 1361 all the old Danish lands, except North Holland, were recovered.

By the recovery of Scania Valdemar had become the lord of the great herring-fishery market held every autumn from St Bartholomew's day (Aug 24) to St. Denis' day (Oct. 9) on the hammer-shaped peninsula projecting from the southwest corner of Scania containing the towns of Skanor and Falsterbo. This flourishing industry, which fully occupied 40,000 boats and 300,000 fishers assembled from all parts of Europe to catch and salt the favourite Lenten fare of the whole continent, was the property of the Danish crown, and the innumerable tolls and taxes imposed by the king on the frequenters of the market was one of his most certain and lucrative sources of revenue. Foreign chapmen eagerly competed for special privileges of Skanor and Falsterbo, and the Hanseatic merchants in particular aimed at obtaining a monopoly there. But Valdemar was by no means disposed to submit to their dictation, and political conjunctures brought about actual hostilities between Valdemar and the Hansa, or at least that portion of it known as the Wendish towns[1], whose commercial interests lay principally in the Baltic.

From time immemorial the Isle of Gotland had been the staple of the Baltic trade, and its capital, Visby, whose burgesses were more than half German, the commercial intermediary between east and west, was the wealthiest city in northern Europe. In July 1361 Valdemar set sail from Denmark at the head of a great fleet, defeated a peasant army before Visby, and a few days later the burgesses of Visby made a breach in their walls through which the Danish monarch passed in triumph The conquest of Gotland at once led to a war between Valdemar and Sweden allied with the Hanseatic towns; but in the spring of 1362 Valdemar repulsed from the fortress of Helsingborg a large Hanseatic fleet provided with "shooting engines" (cannon) and commanded by Johan Wittenburg, the burgomaster of Lübeck. In Sweden proper he was equally successful, and the general pacification which ensued in April 1365, very greatly in his favour, was cemented by the marriage of his daughter Margaret with Hakon VI of Norway.

Valdemar was now at the height of his power Every political rival had been quelled. With the papal see, since his visit to Avignon in 1364, he had been on the best of terms His ecclesiastic patronage was immense, and throughout the land he had planted strong castles surely held by the royal bailiffs. But in the winter of 1367–68 a hostile league against him of all his neighbours threatened to destroy the fruits of a long and strenuous lifetime. The impulse came from the Hansa At a *Hansetag* held at Cologne on Nov. 11, 1367, three groups of the towns, 70 in number, concerted to attack Denmark, and in Jan. 1368 Valdemar's numerous domestic enemies, especially the Jutlanders and the Holstein counts, acceded to the league, with the object of partitioning the realm among them

And now an astounding and still inexplicable thing happened. At Easter-tide 1368, on the very eve of this general attack, Valdemar departed for three years to Germany, leaving his realm in the capable hands of the earl-marshal Henning Podbusk. Valdemar's skilful diplomacy, reinforced by golden arguments, did indeed induce the dukes of Brunswick, Brandenburg and Pomerania to attack the confederates in the rear; but fortune was persistently unfriendly to the Danish king, and peace was finally concluded with the towns by Podbusk and the Danish council of state at the congress of Stralsund, 1370. The con-

[1] Rostock, Greifswald, Wismar and Stralsund.

ditions of peace were naturally humiliating for Valdemar, though ultimately he contrived to render illusory many of the inordinate privileges he was obliged to concede. He was also able, shortly before his death on Oct 24, 1375, to recover the greater part of Holstein from the rebels.

VALDES, JUAN DE (*c.* 1500–1541), Spanish religious writer, younger of twin sons of Fernando de Valdes, hereditary regidor of Cuenca in Castile, was born about 1500 at Cuenca. He has been confused with his twin brother Alphonso (in the suite of Charles V at his coronation in Aix-la-Chapelle, 1520; Latin secretary of state from 1524, died in 1532 at Vienna). Juan, who probably studied at the University of Alcala, first appears as the anonymous author of a politico-religious *Dialogo de Mercurio y Caron*, written and published about 1528. A passage in this work may have suggested Don Quixote's advice to Sancho Panza on appointment to his governorship. The *Dialogo* attacked the corruptions of the Roman Church; hence Valdes, in fear of the Spanish Inquisition, left Spain for Naples in 1530. In 1531 he removed to Rome, where his criticisms of papal policy were condoned, since in his *Dialogo* he had upheld the validity of Henry VIII's marriage with Catherine of Aragon. From the autumn of 1533 he made Naples his permanent residence, his name being Italianized as Valdesso and Val d'Esso.

Valdes' house on the Chiaja was the centre of a literary and religious circle; his conversations and writings (circulated in manuscript) stimulated the desire for a spiritual reformation of the church. His first production at Naples was a philological treatise, *Dialogo de las lenguas* (1533). His works entitle him to a foremost place among Spanish prose writers. His friends urged him to seek distinction as a humanist, but his bent was toward problems of biblical interpretation in their bearing on the devout life. Vermigli (Peter Martyr) and Marcantonio Flaminio were leading spirits in his coterie, which included Vittoria Colonna and her sister-in-law, Giulia Gonzaga. On Bernardino Ochino, for whose sermons he furnished themes, his influence was great. Pietro Carnesecchi, who had known Valdes at Rome as "a modest and well-bred courtier," found him at Naples (1540) "wholly intent upon the study of Holy Scripture," translating portions into Spanish from Hebrew and Greek, with comments and introductions. To him Carnesecchi ascribes his own adoption of the Evangelical doctrine of justification by faith, and at the same time his rejection of the policy of the Lutheran schism. Valdes died at Naples in May 1541.

His death scattered his band of associates. Abandoning the hope of a regenerated Catholicism, Ochino and Vermigli left Italy. Some of Valdes's writings were by degrees published, in Italian translations. They combine a delicate vein of semimystical spirituality with the personal charm attributed to their author in all contemporary notices. Juan Llorente traces in Valdes the influence of Johannes Tauler, any such influence must have been at second hand. The *Avviso* on the interpretation of Scripture, based on Tauler, was probably the work of Alphonso. Valdes was in relations with Fra Benedetto of Mantua, the anonymous author of *Del Beneficio di Gesù Cristo Crocefisso*, revised by Flaminio (reprinted by Babington, Cambridge, 1855). The suggestion that Valdes was unsound on the Trinity was first made in 1567 by the Transylvanian bishop Francis Dávid (*see* article SOCINUS), it has been adopted by Sand (1684), Robert Wallace (1850) and other anti-Trinitarian writers, and is countenanced by Pierre Bayle. But Valdes never treats of the Trinity (even when commenting on Matt. xxviii, 19), reserving it (in his *Latte Spirituale*) as a topic for advanced Christians; yet he explicitly affirms the consubstantiality of the Son, whom he unites in doxologies with the Father and the Holy Spirit (*Opusculos*, p. 145). Practical theology interested him more than speculative, his aim being the promotion of a healthy and personal piety.

The following is a list of his writings:—*Didlogo de Mercurio y Caron* (no date or place, 1528?), *Dialogo de las lenguas* (written, 1533; first printed, Madrid, 1737; reprinted, 1860, 1873), *Qual Maniera si devrebbe tenere a informare . . . gli figliuoli de Christiani delle Cose della Religione* (no date or place; before 1545, as it was used by the Italian translator of Calvin's catechism, 1545), Eng. trans. by J. T. Betts, 1882; *Trataditos* (Bonn, 1881, from a manuscript in the Palatine Library, Vienna, in English, by J. T. Betts, in *XVII Opusculos*, 1882); *Alfabeto Christiano* (written about 1537, in Italian, Venice, 1545, in English, by B. B. Wiffen, 1861); *Ciento i diez concideraciones;* all copies of the original edition suppressed by the Spanish Inquisition; in English by Nicholas Ferrar (at the instance of George Herbert), Oxford, 1638 (another version by J. T. Betts, 1865), *Seven Doctrinal Letters* (original published with the *Trataditos* from Vienna mss. in English, by J. T. Betts, with the *Opusculos*); *Comentario breve . . . sobre la epistola de San Pablo a los Romanos* (Venice, 1556; in English, by J. T. Betts, 1883), *Comentario breve . . . sobre la primera epistola de san Pablo a los Cornitios*, Venice, 1557 (No. 8); *El Evangelio de San Mateo* (1881, from Vienna ms., in English, by J. T. Betts, 1883); *El Salterio* (the Psalms from Hebrew into Spanish published with the *Trataditos* from Vienna manuscript).

Notices of Valdes in Sand (*Biblioth. Antitrinitar.*, 1684), Bayle and Wallace (*Antitrin. Biog.*, 1850) are inadequate. Revival of interest in him is due to McCrie (*Hist Ref. in Italy*, 1827; *Hist Ref in Spain*, 1829). *See* B. Wiffen's *Life* of Valdes prefixed to Betts's translation of the *Considerations* (1865). E. Boehmer, *Spanish Reformers of Two Centuries* (1874), *Lives of J. and A. de Valdes* (1882), and article in *Realencyklopadie fur Prot. Theol. und Kirche* (1885). *See* also M. Young, *Aonio Paleario* (1860); K. Benrath, *Bernardino Ochino* (1875); Menendez Pelayo, *Los Heterodoxos Españoles* (1880), G. Bonet-Maury, *Early Sources of Eng. Unit. Christ* (trans E. P. Hall, 1884). (A. Go.; X.)

VALDEZ, a town of Alaska, farthest north all year open port in North America, situated 61° 07′ N., 146° 16′ W. Pop. (est 1952) 1,600. Selected in 1898 by the U.S war department as a base for exploration, it became the site of a military post, Ft. Liscum, where troops were stationed until 1922. The route of a military telegraph line from Valdez to the settlements of Eagle and Fairbanks became a trail, a wagon road and eventually the principal highway, known as the Richardson highway, open all year between the coast and the interior. Valdez thus became an important port of entry for shipments to Fairbanks, Anchorage and other cities. Gold and copper mining, fish canning and fur farming are important.

VALDIVIA, a province of south Chile. Area 7,723 sq mi., pop. (1950 est.) 214,151. It is roughly mountainous in the east, is heavily forested and is traversed by numerous rivers. There is a chain of lakes across its eastern side near the Andes, the largest of which are Calafquén, Riñihue and Ranco, the boundary between Valdivia and Osorno passing through the centre of the latter. The rivers are the Valdivia or Calle-Calle, with its large tributaries in the central part of the province, and the Bueno which marks the southwestern boundary of the province. The Valdivia (about 100 mi long) has its sources in the Andes and flows west to the Pacific. Its largest tributary on the north is the Río Cruces. The Valdivia is the outlet for Lake Riñihue and is navigable for a long distance. Valdivia is one of the most recently settled provinces and has a large immigrant element, chiefly German. Its most important industry is lumbering. Stock raising is also important, and wheat is grown on the cleared lands. Lumber, cattle, leather, flour and beer are exported. The capital is Valdivia, a flourishing city on the Valdivia river, 12 mi. above its port, Corral, near the mouth of the river. Pop. (1940) 34,496. It is a roughly built pioneer town, in which wood is the principal building material. The mean annual temperature is 52.6° F.; annual rainfall 105 in.

VALDOSTA, a city of southern Georgia, U.S., the seat of Lowndes county. Pop. (1950) 20,046. Valdosta is the seat of the Valdosta State college (opened 1913) and Emory junior college for men. It has large tobacco warehouses.

Its manufactures include cotton, feed, lumber, textiles and metal products. Valdosta was settled in 1859 and was chartered in 1901.

VALENCE, a town of France, on the Rhône. Pop. (1946) 40,020. *Valentia* was the capital of the Segalauni, and the seat of a celebrated school before the Roman conquest, a colony under Augustus, and an important town of *Viennensis Prima* under Valentinian. Its bishopric dates probably from the 4th century. It was ravaged by the Alani and other barbarians, and fell successively under the power of the Burgundians, the Franks, the sovereigns of Arles, the emperors of Germany, the dukes of Valentinois, the counts of Toulouse and its own bishops. To strengthen the hands of the bishops against the dukes of Valen-

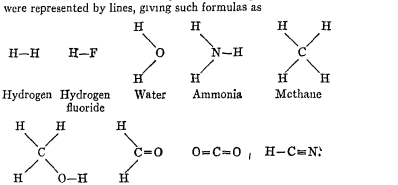
tinois, the pope in 1275 united their bishopric with that of Die. The citizens put themselves under the protection of the dauphin, and in 1456 had their rights and privileges confirmed by Louis XI, the bishops consenting to recognize the suzerainty of the dauphin.

Valence became the capital of the Protestants of the province in 1563. The town was fortified by Francis I. It had become the seat of a celebrated university in the 15th century, but the revocation of the Edict of Nantes crippled the prosperity of the town.

The cathedral of St. Apollinaris, with an interesting apse, was rebuilt in the 11th century in the Romanesque style of Auvergne and consecrated in 1095 by Urban II. It was injured in the wars of religion, but restored in the 17th century.

A curious 16th-century house (Maison des Têtes) has a sculptured front with heads of Homer, Hippocrates, Aristotle, Pythagoras, etc.

VALENCE (or VALENCY), in chemistry, is the property of an element which determines the number of other atoms with which an atom of the element can combine. The property is not a simple one; the effort to obtain a clear understanding of the nature of valence has led in recent years to the dissociation of the concept into several new concepts—of ionic valence, covalence, oxidation number, co-ordination number, metallic valence—corresponding to different modes of interaction of atoms. Some chemists have felt that the word valence might well be allowed to drop into disuse, in favour of these more precise terms. In practice, however, valence continues to be used as a general expression of the combining capacities of the elements or as a synonym for one or another of the more precise terms.



When, toward the middle of the 19th century, the relative weights of atoms and molecules became accurately known, especially through the reintroduction by Stanislao Cannizzaro in 1858 of Amedeo Avogadro's principle (1811) of the relation between the molecular weight and the density of a gas, it became clear that the number of atoms with which a given atom could combine varied with the nature of that atom: that, for example, a fluorine atom could combine with one hydrogen atom, an oxygen atom with two, a nitrogen atom with three and a carbon atom with four, forming the compounds HF, H_2O, H_3N and H_4C. These characteristic combining capacities were shown to extend to more complicated compounds: two of the four hydrogen atoms in methane, CH_4, could be replaced by one oxygen atom, or all four by two, or three by one nitrogen atom, as in H_2CO, CO_2, HCN. Thus, it appeared that every atom could combine with or replace a definite number of other atoms of a specified kind, and hydrogen, since it was the lightest atom and was never found to combine with more than one atom of another element, was selected as the standard. The term valence, or valency, introduced in 1868, is now used to express both the power of combination in general, and its numerical value.

As the examination of the valence of elements was extended there was much dispute as to whether or not it was constant in value for any one element. It soon became evident that the valence of many elements is variable: for a time it was maintained that the variations were always by two units, so that elements could be divided into those of odd and those of even valence; but before long it was recognized that, although this is true of many elements, there are others of which the valence must be admitted to vary by single units at a time.

The discovery of the periodic classification of the elements by Dmitri Mendeleyev and Lothar Meyer (1864–69) brought to light a new regularity in the valences of the elements (*see* PERIODIC LAW, THE). Mendeleyev pointed out that all the elements of a periodic group have the same principal valences, and that these change in value by one unit in passing from one group to the next. In particular, the highest valence of an element, as shown in its oxide, is equal to the ordinal number of the group to which it belongs. On the other hand, the valence in the hydrides seems to rise with that in the oxides from 1 to 4, and then to fall by steps of one unit to unity again.

Earlier Theories.—All discussions of valence in the 19th century were handicapped by the absence of any satisfactory theory of its cause. J. J. Berzelius, in the earlier part of the century, had assumed atoms to be electrically charged, and to be held together in the molecule by the attraction of opposite charges. This view was supported by the phenomenon of electrolysis, as investigated especially by Sir Humphry Davy and Michael Faraday. Its validity as a general theory of valence was, however, destroyed about 1840 by the discovery that under some conditions "electropositive" atoms could be replaced by "electronegative" atoms without any fundamental modification of the properties of the molecule: thus, part of the hydrogen in acetic acid can be replaced by chlorine, and the product resembles the original acid in many ways, and obviously must have a similar structure. The attempts of Berzelius to stretch his theory to explain such phenomena led to its falling into discredit, and it was in part replaced by what ultimately became the theory of structural chemistry.

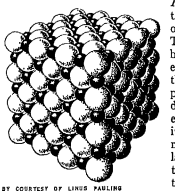
In this new theory no assumptions were made as to the nature of the forces connecting the atoms in a molecule, and hence no opposition in character between the atoms was required. Every atom was regarded as having a certain number of units of combining power, and every atomic link as involving the utilization of one of these units by each of the atoms concerned. Double and triple links, in which each of two atoms used up two or three of these units in combining with one another, were also recognized. The valence of an atom in the numerical sense was the number of such units which it possessed. On paper, the links were represented by lines, giving such formulas as

This theory had an astounding success in its application to organic chemistry. It was found possible to determine from the reactions of a substance the order in which the constituent atoms are linked in the molecule, and thus to assign to the vast hordes of organic compounds "structural formulas" which account for their existence and to a large extent also for their properties. For a discussion of further extensions of this theory, which made it possible to determine the approximate relative positions in space of the various atoms and groups in a molecule, *see* STEREOCHEMISTRY. The electrical theory again became prominent in and after 1887, with the rise of the Svante Arrhenius theory of salt solutions, which showed that a solution of a salt in water contains oppositely charged ions (a solution of sodium chloride, for example, contains positive sodium and negative chlorine ions) which have to a great extent the properties of free molecules.

(N. V. S.; L. C. P.)

Werner's Co-ordination Theory.—A new concept in chemistry was developed in 1893 by Alfred Werner. It had been recognized that many metallic salts have the power of combining with other salts or with water or ammonia or other molecules. The compounds formed in this way had not been fitted into any theory of valence, however, and their existence had been attributed to the action of weak residual forces, inferior to the forces of true valence. By the study of an immense number of these compounds, Werner showed that their compositions and properties could be systematized on the basis of a new assumption. This assumption, which was later completely verified by X-ray investigations of the structure of complex crystals (R. W.

G. Wyckoff and R. G. Dickinson, 1920), is that a metal atom has the power of combining with a definite number (usually 4 or 6) of other atoms, ions or molecules, and "co-ordinating" them into a definite geometrical arrangement about itself. Werner was able to present sound evidence, consisting mainly of the existence of isomers, to support his proposal that most complexes with "co-ordination number" 6, such as the hexachloroplatinate ion, $[PtCl_6]^{--}$, and the cobaltic hexammine ion, $[Co(NH_3)_6]^{+++}$, have an octahedral configuration, the six attached groups being arranged at the corners of a regular octahedron about the central atom. He also showed that some complexes with co-ordination number 4 have a tetrahedral configuration (such as $[Zn(NH_3)_4]^{++}$) and some have a square, planar configuration ($[PtCl_4]^{--}$ and other complexes of bivalent palladium and platinum). General acceptance of Werner's co-ordination theory came in 1911, after his prediction and the experimental verification of the existence of the optical isomerism of some octahedral co-ordination complexes (*see* Co-ordination Compounds; Stereochemistry)



The Development of the Electronic Theory of Valence.—The modern electronic theory provides a detailed and thoroughly sound explanation of valence and chemical combination in terms of the electrostatic forces operating between electrons and atomic nuclei. The first great step in the development of this theory was made by Gilbert Newton Lewis by the identification of the valence bond of the organic chemist with a pair of electrons held jointly by two atoms, and serving to hold them together. Lewis also discussed the relation between the electronic structure of atoms and the valence of elements, including their power to form ions. In the same year (1916) the electronic structure of ions was discussed by W. Kossel; and after the development of the detailed electronic theory of the periodic system of the elements (*see* Periodic Law, The) further progress in the formulation of the electronic theory of valence was rapidly made through the efforts of I. Langmuir, N. V. Sidgwick and many other chemists.

Within two years after the development of quantum mechanics (*q.v.*) by W. Heisenberg, E. Schrodinger and P. A. M. Dirac, the fundamental nature of the shared-electron-pair chemical bond was elucidated by the quantum-mechanical treatment of the hydrogen molecule, carried out by W. Heitler and F. London in 1927. During the next few years many workers contributed to the application of quantum mechanics to the problem of chemical combination and valence, and rapid progress was made in the discovery of the principles determining the formation of shared-electron-pair bonds, the relation of the nature of bonds to the character of bond orbitals, and the significance of quantum-mechanical resonance to molecular structure. As a result of this progress and the great progress which has been made in the determination of the detailed atomic structures of molecules and crystals by methods of spectroscopy and the diffraction of X-rays and electrons, the theory of chemical valence is no longer a discussion of empirical rules, but is in large part a precise discussion of electronic structures and interatomic forces firmly based on the modern knowledge of electrons and atomic nuclei and their interactions.

Ionic Valence.—Molten sodium chloride is a good conductor of electricity. This molten salt consists of monatomic ions, positive sodium ions, Na^+, and negative chloride ions, Cl^-, in a moderately compact aggregate, in which, because of thermal agitation, each ion is free to move slowly around. Under the influence of the applied electrical field the sodium ions move toward the negative electrode and the chloride ions toward the positive electrode, and this motion of the ions carries the electric current through the region between the electrodes.

A sodium ion is a sodium atom which has lost one electron, and has thus acquired an electric charge $+e$ (or $+1$, with use of the magnitude of the electronic charge as unity). Since sodium is one greater in atomic number than neon, the sodium ion contains the same number of electrons as the neon atom. The chloride ion is a chlorine atom which has gained one electron, and has thus assumed a negative charge $-e$ (or -1), and the same number of electrons as argon. It is not accidental that these ions have the same electron numbers as the noble gases neon and argon. The noble gases are shown by their extreme chemical inertness to have especially stable electronic structures. This stability is shown by the fact that the ionization energy (the energy required to remove one electron from the atom: $X \rightarrow X^+ + e^-$) is greater for the noble gases than for any other atoms. Similarly, the electron affinity—the energy liberated in picking up an additional electron, according to the reaction $X + e^- \rightarrow X^-$—is smaller for the noble-gas atoms than for other atoms. An atom with atomic number near that of a noble gas tends to achieve the noble-gas structure by the loss or gain of electrons. One electron of a neutral sodium atom is loosely held and can be removed by a rather small amount of work; the ionization energy of the sodium atom is small. The chlorine atom has the power of adding an electron. When metallic sodium and gaseous chlorine react, an electron is transferred from each sodium atom to a chlorine atom, forming the ions Na^+ and Cl^-. Sodium chloride is an aggregate of these ions. The necessity of electrical neutrality requires that the substance contain equal numbers of singly charged cations and singly charged anions—hence, its formula is Na^+Cl^- (usually written NaCl); only a minute excess of ions of one sign would cause the sample of salt to have a high electrical potential.

The coulomb forces between the ions cause each ion to attract neighbouring ions of opposite sign, and to tend to co-ordinate them about itself. This leads to a stable spatial arrangement, shown by the sodium-chloride crystal (*see* figure), in which each ion has 6 nearest neighbours of the opposite sign, and 12 neighbours of the same sign at a distance $\sqrt{2}$ larger. The total coulomb energy for this arrangement is found by summation over pairs of ions to be $-1.7476\frac{e^2}{R}$ per Na^+Cl^- ion pair, in which R is the distance between the centre of one ion and the centre of one of its six nearest neighbours. The crystal is hence stabilized by this coulomb attraction by an energy quantity 75% greater than the coulomb energy of a positive and a negative charge the distance R apart. This coulomb energy of the crystal is large—it amounts to -205 kg.cal per mole for sodium chloride, and is large enough (with the help of the electron affinity of chlorine) to provide the energy to sublime sodium metal to separate atoms, to ionize these atoms and to dissociate chlorine molecules into chlorine atoms, all with 98 kg.cal per mole to spare, which is evolved as the heat of formation of sodium chloride from the elements.

BY COURTESY OF LINUS PAULING

THE ATOMIC ARRANGEMENT IN THE SODIUM-CHLORIDE CRYSTAL: SMALL SPHERES ARE SODIUM IONS, LARGE SPHERES CHLORIDE IONS

The forces of attraction of ions of opposite charge are called "ionic valence forces," and the charge of an ion is called its "ionic valence." Sodium and the other alkali metals, with atomic number one greater than the noble gases, tend to form ionic compounds in which they have ionic valence $+1$ (are "unipositive"). Chlorine and the other halogens form compounds in which they have ionic valence -1 (are "uninegative"). The alkaline-earth metals lose two electrons per atom, to form the bipositive ions Be^{++}, Mg^{++}, Ca^{++}, Sr^{++}, Ba^{++} and Ra^{++}, in compounds such as $Ca^{++}Cl_2^-$, $Ca^{++}O^{--}$, etc. The elements of Group VI of the periodic table may form binegative ions O^{--}, S^{--}, Se^{--} and Te^{--}.

The metals of Groups Ib and IIb (*see* Periodic Law, The) tend to form cations (Cu^+, Ag^+, Zn^{++}, Cd^{++}, Hg^{++}) in which they have ten more electrons than a noble gas. The transition elements also form cations with other electron numbers. Usually these ions are bipositive or terpositive—the electron affinity of electronegative elements and the stabilizing effect of interionic attraction seem to be sufficient to remove two or three electrons from a transition atom, but not more. Examples of stable ions

are Cr^{+++}, Mn^{++}, Fe^{++}, Fe^{+++}, Co^{++}, Ni^{++} and Cu^{++}. The rare-earth metals usually form terpositive ions; a few, such as cerium, also form quadripositive ions, and a few others, such as europium, form bipositive ions.

Covalence.—Another kind of valence of great importance is "covalence," which results from the sharing of two electrons by two atoms. The bond which consists of a pair of shared electrons is called a "covalent bond"; it is essentially the bond of the organic chemist, represented by a dash in structural formulas,

such as H—C—C—O—H for ethyl alcohol.

Whereas in an ionic compound the individual ions retain some independence of one another, and under certain conditions (as in the molten salt or in solution in a solvent of high dielectric constant) can move about rather freely, the atoms which are bonded together by covalent bonds are held tightly to one another and form a rather rigid molecule.

The simplest example of a covalent molecule is the hydrogen molecule, H_2, for which the structure H:H or H—H can be written. This molecule has been found by experiment to be rigid, with the equilibrium internuclear distance 0.740 A, the frequency of nuclear vibration $4{,}318\ cm.^{-1}$ (corresponding to a large restoring force to the equilibrium configuration) and the energy of dissociation of the molecule in its normal state into atoms 102,700 cal. per mole. The quantum-mechanical treatment of this molecule, carried out by Heitler and London and refined by H. M. James and A. S. Coolidge, has given complete agreement with these experimental values, leaving no doubt that the chemical bond in this molecule is the shared-electron-pair bond postulated by G. N. Lewis and formulated mathematically by the theory of quantum mechanics.

The rules which determine the formation and properties of covalent bonds may be stated as follows: a covalent bond between two atoms consists of two electrons (with opposed spins—*see* ELECTRON, THE), occupying one orbital for each atom. The strength of the bond is determined by the stability of the atomic orbitals, and also by their nature, a good bond orbital of an atom being a stable orbital which extends in the direction of the atom with which the bond is formed.

The requirement of stability of bond orbitals (as well as of atomic orbitals occupied by electron pairs not shared with other atoms) causes the covalence of atoms to be related to certain stable electronic configurations, especially those of the noble gases. Since an atomic orbital can be occupied by either an unshared electron pair or a shared electron pair, a noble-gas configuration can be achieved by an atom by the formation of covalent bonds as well as by the transfer of electrons (ionic valence). The normal covalences 4, 3, 2 and 1, respectively, for carbon, nitrogen, oxygen and fluorine, correspond to the achievement of the neon structure by the sharing of electrons:

A double bond between two atoms involves two electron pairs,

and two orbitals for each atom, as in ethylene, C::C, a triple

bond involves three electron pairs, and three orbitals for each atom, as in hydrogen cyanide, H:C:::N:. In each of these molecules the hydrogen atom achieves the helium configuration by forming one shared pair, and the carbon and nitrogen atoms achieve the neon configuration.

An atom may form covalent bonds in number different from the normal number, and complete its stable electronic configuration by the transfer of electrons. An example is nitrogen in the ammonium ion, $\left[\begin{smallmatrix} & H & \\ H & : & H \\ & H & \end{smallmatrix}\right]^+$.

When uncertainty arises as to the most satisfactory electronic structure for a molecule, the question may usually be resolved by assigning to a molecule a hybrid structure, corresponding to resonance among the likely alternative structures (*see* RESONANCE, THEORY OF). Thus, hydrogen chloride may be assigned the structure $\{H^+Cl^-, H-Cl\}$, a hybrid of the structure involving an extreme ionic bond and that involving a normal covalent bond; nitrous oxide may be assigned the structure $\{:\dot{N}=N=\ddot{O}, \cdot N\equiv N-\ddot{O}:\}$, a hybrid of the two most reasonable valence-bond structures. Some progress has been made in the rough quantitative assignment of hybrid structures, with use of experimental values of energy of formation, interatomic distances and other molecular properties.

For some purposes it is convenient to make use of the concept of formal charge. The formal charge of an atom is the electrical charge which the atom would have if it retained all its unshared electrons and one-half the electrons which it shares with atoms to which it is bonded. For example, in the ammonium ion, with the structure shown above, the formal charge of the hydrogen atoms is 0, and that of the nitrogen atom is +1.

Co-ordination Number.—The "co-ordination number" of an atom is the number of atoms, ions or molecules which the atom holds as its nearest neighbours in a complex or a crystal. Thus, the metal atom has co-ordination number 8 in the Werner co-ordination complexes $[Mo(CN)_8]^{4-}$ and $[Sr(H_2O)_8]^{++}$; 7 in the complex $[ZrF_7]^{3-}$; 6 in the complexes $[SnCl_6]^{--}$, $[PtBr_6]^{--}$, $[FeF_6]^{---}$, $[Co(NH_3)_6]^{+++}$ and $[Al(H_2O)_6]^{+++}$; 4 in the complexes $[Zn(CN)_4]^{--}$, $[Cu(CN)_4]^{---}$, $[Ni(CN)_4]^{4-}$, $[Ni(CN)_4]^{---}$, $[Be(H_2O)_4]^{++}$, $[BF_4]^-$ and $[Pt(CN)_4]^{--}$; and 2 in the complexes $[Ag(NH_3)_2]^+$, $[AuCl_2]^-$ and $[HgCl_2]$.

The forces which hold the atoms together in these complexes and which lead to the observed co-ordination numbers are of different kinds. The bonds to the highly electronegative fluorine atoms in the fluoride complexes are essentially ionic, and the increase in co-ordination number, with fluoride ion, from 5 to 6 to 7 for B^{+++}, Fe^{+++} and Zr^{4+}, is the result mainly of the increase in size of the cation, which permits a successively larger number of fluoride ions F^- to be packed about the central ion. The influence of the relative size of the co-ordinated molecule and the central ion is also important in the hydrated cations, in which the co-ordinating bond is mainly the electrostatic attraction of the central cation and the negative end (the oxygen atom) of the water molecule.

In many Werner complexes, including those formed by cyanide ion, the nitrite ion or nitro group, the thiocyanate ion, the halide ions (other than fluoride), the ammonia molecule and the carbon monoxide molecule, the bonds between the attached atom or group and the central atom are essentially covalent, and the co-ordination number is determined by the nature of the bond orbitals of the central atom. Thus, Zn^{++} and Cu^+ have their five 3*d* orbitals occupied by unshared pairs of electrons, leaving as stable orbitals suited to bond formation the one 4*s* and the three 4*p* orbitals. These can hybridize to form four bond orbitals directed toward the corners of a regular tetrahedron; accordingly, these ions form cyanide complexes $[Zn(CN)_4]^{--}$ and $[Cu(CN)_4]^{---}$, with co-ordination number 4 and the tetrahedral configuration.

The neutral nickel atom similarly forms tetrahedral complexes $[Ni(CN)_4]^{4-}$ and $[Ni(CO)_4]$. However, the bipositive nickel ion Ni^{++} behaves differently. It may use one 3*d* orbital for bond formation; this orbital can hybridize with the 4*s* orbital and two 4*p* orbitals to form four bond orbitals directed toward the four corners of a square which is coplanar with the central ion. It was discovered by Werner that bivalent palladium and platinum form these square planar complexes, and this configuration has been verified for the covalent complexes of bivalent nickel also.

The octahedral covalent complexes, such as the ferrocyanide ion, $[Fe(CN)_6]^{4-}$, involve six covalent bond orbitals formed by hybridization of two 3*d* orbitals with the 4*s* and 4*p* orbitals.

Some heavy-metal atoms tend to assume coördination number 2 and to form two oppositely directed covalent bonds. Examples of such linear complexes are: $[:N{\equiv}C-Cu-C{\equiv}N:]^-$, $[:N{\equiv}C-Ag-C{\equiv}N:]^-$, $[Cl-Au-Cl]^-$ and $[Cl-Hg-Cl]^0$.

Oxidation Number.—After the concepts of ionic valence and covalence had been introduced, and detailed electronic structures of molecules began to be written, it was recognized that a simple representation of the oxidation states of elements in a compound is needed, especially as an aid in balancing equations for oxidation-reduction reactions. The "oxidation number" has come into use for this purpose.

The oxidation number of an element in a substance is the electrical charge assigned to the atoms of the element according to certain rules. These rules are simple, but are not completely unambiguous, and their application requires some chemical insight. The rules, as generally accepted, are the following:

1. The oxidation number of a monatomic ion in an ionic substance is equal to its electrical charge.

2. The oxidation number of atoms in an elementary substance is zero.

3. In a covalent compound of known structure, the oxidation number of each atom is the charge remaining on the atom when each shared electron pair is assigned completely to the more electronegative of the two atoms sharing it (*see* PERIODIC LAW, THE) A pair shared by two atoms of the same element is usually split between them.

4. The oxidation number of one element in a compound of uncertain structure may be calculated from a reasonable assignment of oxidation numbers to the other elements in the compound.

For example, in the permanganate ion, MnO_4^-, oxygen is assigned its usual oxidation number -2, manganese, hence, has oxidation number $+7$. In acidic solution this ion can be reduced to manganous ion, Mn^{++}, by a suitable reducing agent. Hydrogen peroxide can serve as the reducing agent for this purpose. The oxidation number of oxygen in hydrogen peroxide, H_2O_2, is -1, that of hydrogen being $+1$, and on oxidation of hydrogen peroxide free oxygen is formed, with increase in oxidation number of oxygen from -1 to 0. Hence, two manganese atoms can oxidize ten oxygen atoms, and the equation for the oxidation of hydrogen peroxide by permanganate ion in acidic solution is easily written:

$$2MnO_4^- + 5H_2O_2 + 6H^+ \rightarrow 2Mn^{++} + 5O_2 + 8H_2O.$$

The word valence when used in the field of inorganic chemistry ordinarily refers to the state of oxidation of an element as expressed by its oxidation number, whereas in organic chemistry it ordinarily refers to the covalence of the element.

The Hydrogen Bond.—A structural feature which has an important effect on the properties of many substances is the "hydrogen bond." A hydrogen atom bonded to an electronegative atom can attract another electronegative atom, and form with it a weak bond (with bond energy 5 or 10 kg cal. per mole). This bond is not a second covalent bond—hydrogen, with only one stable orbital, can form only one covalent bond—but is the result of the attraction of the residual positive charge of the hydrogen atom bonded to one electronegative atom for an unshared electron pair of the other atom.

The strongest hydrogen bonds are formed by fluorine ($[FHF]^-$, polymers of HF). The hydrogen bonds formed by water molecules are responsible for the surprisingly high melting point of ice and boiling point of water, for the existence of a maximum density of water and for the expansion of water on freezing (*see* ICE). Many special properties of inorganic and organic molecules, such as the dimerization of fatty acids, are caused by hydrogen-bond formation.

Metallic Valence.—The nature of the valence forces operating in metals, and especially in intermetallic compounds, has not as yet (mid-20th century) been completely elucidated. It seems certain, however, that metals and intermetallic compounds can be described as aggregates of metal cations bound together by valence electrons, which have considerable freedom of motion through the specimen, and it is reasonable to call the number of electrons of an atom which help to bind the metallic crystal together the "metallic valence" of the atom.

It is likely that the metallic valence of the alkali metals is 1, and that that of the alkaline-earth metals is 2. Values for the transition metals are uncertain, but their strength and hardness suggest values increasing from 3 for scandium to about 6 for chromium and succeeding elements, and then decreasing for copper and zinc. The magnetic properties of the rare-earth metals provide evidence that the metallic valence is 3 for all the rare-earth metals except europium and ytterbium, and is 2 for these two metals, the paramagnetic susceptibility of these two metals is the same as for their bivalent salts, whereas for the other rare-earth metals it is the same as for their tervalent salts.

Some progress has been made in systematizing the often complex formulas of intermetallic compounds such as γ-brass, Cu_5Zn_8, and the compounds $Cu_{31}Sn_8$, Cu_9Al_4, Fe_2Zn_{21}, etc., which are related to it (*see* ALLOYS) It was pointed out (A Westgren, W. Hume-Rothery) that if the valences 1, 2, 3 and 4 are assigned to Cu, Zn, Ga and Sn, respectively, the formulas Cu_5Zn_8, Cu_9Ga_4, and $Cu_{31}Sn_8$ all correspond to the same ratio, $\frac{21}{13}$, of valence electrons to atoms, and a quantum-mechanical theory of the stability of these alloys in terms of electron waves was developed by H. Jones. An equivalent theory was formulated with the use of another set of metallic valences, originally deduced from the ferromagnetic properties of the transition metals (L. Pauling). These valences, 5.44, 4.44, 3.44 and 2.44 for Cu, Zn, Ga and Sn, respectively, also lead to a constant value, $62\frac{1}{13}$, for the ratio of valence electrons to atoms in the γ-alloys, with the formulas given above Further progress toward a penetrating understanding of the nature of metals was needed before a firm choice between the metallic valences 1 and 5.44 for copper (and similar pairs of values for other transition elements) could be justified.

It is clear that valence does not play as great a part in determining the compositions of intermetallic compounds as it does for salts and organic compounds. Among the other factors of significance for intermetallic compounds the relative sizes of atoms of different kinds is of greatest importance; many intermetallic compounds have compositions corresponding to modes of filling space with atoms of different sizes in such a way as to give each atom the maximum number of neighbours.

From the consideration of interatomic distances V. M. Goldschmidt was led to conclude that the metallic bond is closely related to the covalent bond. Usually the number of neighbours of an atom in a metal or alloy is greater than its metallic valence, and the covalent bonds formed by the atom are considered to resonate among the interatomic positions.

(L. C. P.)

VALENCIA, the name of a maritime province of eastern Spain, and anciently of a kingdom. Pop. (1950) 1,337,339; area, 4,239 sq mi. When the ancient kingdom of Valencia was incorporated into Aragon in 1238, it included the provinces of Castellón de la Plana (*q.v.*) and Alicante (*q.v.*). It was bounded inland on the north by Catalonia, west by Aragon and New Castile, and south by Murcia. This region had an area of 8,964 sq mi and a population of approximately 2,000,000 in 1939. For its history *see* VALENCIA (city).

The inhabitants are of very mixed race, owing to the successive occupation of the country by Iberians, Greeks, Carthaginians, Romans, Visigoths and Moors. Their dialect resembles Catalan but is softer, and contains a larger percentage of Arabic words

The elaborate irrigation works and the system of intensive agriculture which have rendered the *huertas* or gardens of Valencia celebrated were initiated by the Moors; the fame of the Elche date groves, the Alicante vineyards and the Valencia orange plantations, was also originally due to them.

With the decline of the caliphate of Cordova early in the 11th century, Valencia became an independent kingdom which passed

successively into the power of the Almoravides and Almohades

In 1609, 200,000 Moriscos, or Moors who outwardly professed Christianity, were banished from the country. In 1833 Valencia was divided into the three provinces already named

The coast is skirted by considerable stretches of sand dune, and by a series of these the lagoon called the Albufera de Valencia (*q.v.*) is separated from the Mediterranean. The principal rivers are the Guadalaviar or Turia and the Júcar (*q v.*). Irrigation disputes are settled by the peasants' Tribunal de las Aguas which meets weekly in front of Valencia cathedral.

The *vegas* (cultivated plains) have an exceptionally fine, almost subtropical climate In their low-lying portions rice is the favourite crop; elsewhere wheat, maize and all kinds of fruit; the mulberry is cultivated for silk; and wine and oil are produced. Esparto grass is grown in the less fertile areas The fishing industry is considerable, and there are manufactures of silk, carpets and tapestry, woollen, hemp and linen fabrics, glass, pottery and leather, there are also iron foundries, distilleries, cooperages and oil refineries. The coast railway from Barcelona traverses the province. Valencia, the capital and principal seaport, and the towns of Alcira, Sueca, Játiva, Carcagenta, Cullera, Onteniente, Sagunto and Gandía, are described in separate articles Other towns are Algemesí (15,443), Catarroja (10,078). Oliva (17.557), Liria (10,451), Tabernes de Valldigna (10,885) and Torrente (12,781).

VALENCIA, capital of the Spanish province of Valencia, on the Guadalaviar or Turia, 3 mi. from the Mediterranean sea, and 304 mi. E.S.E of Madrid by rail. Pop (1930) 320,195; (1950) 465,000 (mun., 590,975) Earliest mention of Valencia (*Valentia*) is by Livy (*Epit.*, lv), who states that Junius Brutus settled the soldiers of Viriathus there in 138 B.C., and invested the town with the *jus Latinum*. It sided with Sertorius (*c* 77 B.C.), and was accordingly taken and partially destroyed by Pompey in 75 B.C.; but it must have recovered speedily, as it is mentioned by Pliny (iii, 4) as a colony in the region of the Edetani, and by Mela as an important place. It was taken by the Visigoths in A.D. 413, and by the Moors in 714 An independent Moorish kingdom of Valencia was established in 1021, and extended from Almería to the Ebro estuary The Almoravides occupied the city in 1094, but it was retaken within a few months by the Christians under the Cid (*q v*), from whom it is sometimes called Valencia del Cid The Moors recovered possession in 1101 and the kingdom was re-established in 1146. After 1172 it became tributary to Aragon, and in 1238 James I of Aragon added it to his dominions. The first Spanish printing press is said to have been set up there in 1474. Toward the close of the 15th century Valencia was annexed to Castile. In the 16th and 17th centuries it was the seat of a school of painting. In the War of Succession Valencia sided with the house of Austria. It was captured by the French in 1812 and held till 1813. In Nov. 1936 it was made the loyalist capital for a time. The nationalists captured it in 1939.

Valencia is the seat of an archbishop, a court of appeal, a university, a captain-general and an army corps. All around it stretches Huerta de Valencia, an alluvial plain with groves of oranges, lemons and mulberries. The climate is mild and very dry; rain hardly ever falls. The white houses, often Moorish in architecture, and the multitude of domes and towers give to Valencia an oriental appearance. Until 1871 it was enclosed by a Roman wall rebuilt in 1356 by Pedro IV; two picturesque gateways with machicolated towers still remain. The cathedral (La Seo), begun in 1262, possesses examples of 15th-century sculpture and metalwork, as well as of the Valencian school of painting. The campanile (el Miguelete), an isolated octagonal Gothic tower, is 152 ft. in height.

Valencia university was formed about 1500. It began to decline in 1600 but was reorganized after 1848, and resumed its place as one of the leading universities. There is a provincial museum, with paintings by Velazquez, Ribera, Dürer, Juanes, Bosco, Goya and many modern artists.

The principal manufacture is silk. The town is also celebrated for its coloured tiles or "azulejos," its oranges and onions. Linen, woollen and esparto fabrics, hats, fans, leather, paper, cigars, glass and pottery are also manufactured, and there are foundries and printing works. Corn, rice, silk, saffron, oranges, raisins, almonds, figs and other fruits are exported, and iron, hardware, timber, manure, grain and colonial produce are imported.

The port of Villanueva del Grao is 3 mi. E by N. of Valencia. Spanish and British coasters chiefly call there.

VALENCIA, a city of Venezuela and capital of the state of Carabobo; pop (1950), 84,927 The city is connected by railway to Lake Valencia, which is 1,348 ft. above sea level, 30 mi long, and has an area of 216 sq mi. The city is situated in a large valley between parallel ranges of the Maritime Andes, about 1,625 ft. above sea level, and in the midst of plantations and luxuriant vegetation. There are extensive manufacturing industries.

Valencia was founded in 1555 by Alonzo Diaz Moreno, being 12 years older than Caracas It was occupied for a time in 1561 by Lope de Aguirre and his band of outlaws. At the beginning of the War of Independence it was made the capital of Venezuela, and the patriot congress was in session there on March 26, 1812, when Caracas was destroyed by an earthquake In 1830 Valencia was the scene of the Constituent congress, again in 1856 it was the meeting place of the National convention and served the same purpose in 1870.

VALENCIA or VALENTIA, an island, County Kerry, Ireland, forming the southern horn of Dingle bay It is 7 mi. long and 3 mi. broad. It forms with the mainland a fine natural harbour, land-locked with narrow entrances, and a depth of about 40 ft at low tide. At its north end is the Valencia Harbour station, while across the strait is Knightstown, on the island. The harbour is used by fishing vessels From Valencia the "Great Eastern" laid the cable to Newfoundland in 1866 On the island is a meteorological station. Its name is Spanish; the Irish called it Dairbhre, the oak forest. Pop (1936) 1,778.

VALENCIA DE ALCÁNTARA, a town of western Spain, in the province of Cáceres. Pop. (1940), 6,904 (mun , 15,415) From the 16th century to the 18th Valencia was a celebrated border fortress, it was captured by the Portuguese in 1664 and 1698. Valencia de Alcántara is an important customhouse between Spain and Portugal, and has a flourishing trade in farm produce, and in phosphates from the mines. A Roman aqueduct still brings water to the main street; the courtyards and windows of many houses are Moorish in style.

VALENCIENNES, a town of northern France. Population (1940) 38,684.

Valenciennes is said to owe its name and foundation to one of the three Roman emperors named Valentinian In the middle ages it was the seat of a countship which in the 11th century was united to that of Hainaut. In the 16th century Valenciennes became the stronghold of Protestantism in Hainaut, but was conquered by the Spaniards. In 1656 the Spaniards under the prince of Condé made a successful defense against the French under Vicomte de Turenne; but in 1677 Louis XIV took the town and Vauban constructed the citadel.

Valenciennes, which then became the capital of Hainaut, has since always belonged to France. In 1793, after 43 days' bombardment, the garrison surrendered to the allied forces. In 1815 it defended itself successfully.

The Scheidt there divides into two branches, one of which flows through the town, while the other, canalized and forming a port, skirts it on the west. The Tour de la Dodenne (13th and 15th centuries) and the citadel (17th century) are the chief remains of the old fortifications. The town hall is early 17th century, with a 19th-century façade. The museum contains a good collection of paintings.

Valenciennes is the centre of the rich Anzin coal field. There are important foundries, forges, rolling mills, wireworks and machine shops. There is also an extensive sugar beet cultivation, with attendant sugarworks and distilleries, and glass, starch, chemicals and soap are produced. Hosiery, trimmings and handkerchiefs are manufactured and cotton weaving and printing are carried on, though little of the famous lace is now made.

VALENCY: *see* VALENCE.

VALENS, East Roman emperor from 364 to 378, owed his elevation in the 36th year of his age to his brother, Valentinian, who chose him to be his associate in the empire. Valens had been attached to Julian's bodyguard, but he did not inherit the military ability of his father, Gratian of Pannonia. A revolt headed by Procopius in the second year of his reign was quelled by the ability of his generals In the year 366 Valens at one stroke reduced the taxes of the empire by one-fourth, a very popular measure, though one of questionable policy in the face of the threatening attitude of the Goths on the lower Danube. Before venturing on a campaign against them, Valens received baptism from Eudoxus, the Arian bishop of Constantinople After some small successes over the Goths, won by his generals (367–369), Valens concluded a peace with them, which lasted six years, on a general understanding that the Danube was to be the boundary between Goths and Romans On his return to Constantinople in 369–370 Valens began to persecute his orthodox and Catholic subjects, but he lacked the energy to carry out his edicts.

In the years 371 to 377 Valens was in Asia Minor, most of the time at the Syrian Antioch Though anxious to avoid an Eastern war, because of danger nearer home from the Goths, he was compelled to take the field against Shapur II. Valens crossed the Euphrates in 373, and drove back the king of Persia to the farther bank of the Tigris. But the Roman success was by no means decisive, and no definite understanding as to boundaries was come to with Persia Valens returned to Antioch, where in the winter of 373–374 he instituted a persecution of magicians. Between 374 and 377 we read of grievous complaints of injustice and extortion perpetrated under legal forms Although preparations were made for following up the war with Persia and securing the frontier, a truce was patched up, rather to the disadvantage of the empire, Armenia and the adjacent country being half conquered and annexed by Shapur. The armies of Rome, in fact, were wanted in another quarter The Huns, of whom we now hear for the first time, were beginning in 376 to press the Goths from the north, and the latter asked leave of the emperor to cross the Danube into Roman territory This they were allowed to do, on the condition that they came unarmed, and their children were transported to Asia as hostages. The conditions, however, were not observed by the imperial generals Accordingly, the enraged Goths, under their chief Fritigern, poured across the Balkans into Thrace and the country round Adrianople, plundering, burning and slaughtering as they went They were driven back for a time, but returned in the spring of 378 in greater force, with a contingent of Huns and Alans; and penetrated to the neighbourhood of Adrianople Valens left Constantinople in May 378 with a strong and well-officered army. Without awaiting the arrival of his nephew Gratian, emperor of the West, who had just won a great victory over the Alamanni, Valens attacked the enemy at once. The battle, which was fought on confined ground in a valley, was decided by a cavalry charge of the Alans and Sarmatians, which threw the Roman infantry into confusion and hemmed it in so closely that the men could scarcely draw their swords. The slaughter, which continued till the complete destruction of the Roman army, was one of the greatest recorded in antiquity Valens perished either on the field or, as some said, in a cottage fired by the enemy From the battle of Adrianople the Goths permanently established themselves south of the Danube

See Ammianus Marcellinus, bks. 26–31; E. Gibbon, *The Decline and Fall of the Roman Empire* (ed Bury, London, 1909), chs. 25–26; Hodgkin, *Italy and Her Invaders* (1880; and ed., 1892–99), vol. i ; F. Runkel, *Die Schlacht bei Adrianopel* (Berlin, 1903).

VALENTINE or VALENTINUS, the name of a considerable number of saints. The most celebrated are the two martyrs whose festivals fall on Feb. 14, the one, a Roman priest, the other, bishop of Terni (Interamna). The *Passion* of the former is part of the legend of SS Marius and Martha and their companions; that of the latter has no better historical foundation; so that no argument can be drawn from either account to establish the differentiation of the two saints It would appear from the two accounts that both belonged to the same period, *i.e.*, to the reign of the emperor Claudius (Gothicus); that both died on the same day; and that both were buried on the Via Flaminia, but at different distances from Rome The *Martyrologium Hieronymianum* mentions only one Valentinus. "Interamnae miliario LXIIII. via Flaminia natale Valentini." The St. Valentinus who is spoken of as the apostle of Rhaetia, and venerated in Passau as its first bishop, flourished in the 5th century. For the observances connected with St. Valentine's Eve and Day, *see* John Brand's *Popular Antiquities* (edited by W. C. Hazlitt, vol. ii. pp. 606–11, London, 1905), W. Hone's *Every-Day Book*, and Chamber's *Book of Days*. The association of the lovers' festival with St Valentine seems to arise from the fact that the feast of the saint falls in early spring, and is purely accidental.

See *Acta Sanctorum*, February, ii. 753, 756, and January, i 1094; G. B. de Rossi, *Bullettino di archeologia cristiana* (1877), p 101 and (1878), p. 59.

VALENTINE AND ORSON, a romance attached to the Carolingian cycle It is the story of twin brothers, abandoned in the woods in infancy. Valentine is brought up as a knight at the court of Pippin, while Orson grows up in a bear's den to be a wild man of the woods, until he is overcome and tamed by Valentine, whose servant and comrade he becomes. The two eventually rescue their mother Bellisant from the power of a giant. There are versions of the tale, which appears to rest on a lost French original, in French, English, German, Icelandic, Dutch and Italian. In the older versions Orson is described as the "nameless" one

The French romance was printed at Lyons in 1489. *The Historye of the two Valyaunte Breitheren · Valentyne and Orson . . .* by Henry Watson (*c.* 1550) is the earliest known English version. A ballad on the subject was printed in Percy's *Reliques* For a detailed bibliography of the English, French, German, Dutch and Italian forms of the tale, *see* W. Seelman, "Valentin und Namelos" (Norden and Leipzig, 1884), in vol iv of *Niederdeutsche Denkmaler.*

VALENTINIAN I., Roman emperor of the West from A D 364 to 375, was born at Cibalis, in Pannonia. He had been an officer of the guard under Julian and Jovian, and had risen high in the imperial service He was chosen emperor in his forty-third year by the officers of the army at Nicaea in Bithynia in 364, and shortly afterwards named his brother Valens (*q.v.*) colleague with him in the empire As emperor of the West, Valentinian took Italy, Illyricum, Spain, the Gauls, Britain and Africa, leaving to Valens the eastern half of the Balkan Peninsula, Greece, Egypt, Syria and Asia Minor as far as Persia. During the short reign of Valentinian there were wars in Africa, in Germany and in Britain, and Rome came into collision with the Burgundians, Saxons and Alamanni The emperor's chief work was guarding the frontiers and establishing military positions Milan was at first his headquarters for settling the affairs of northern Italy; next year (365) he was at Paris, and then at Reims, to direct the operations of his generals against the Alamanni who were driven back to the German bank of the Rhine, and checked for a while by a chain of military posts and fortresses At the close of 367, however, they suddenly crossed the Rhine, and sacked Moguntiacum (Mainz). Valentinian attacked them at Solicinium (Sulz in the Neckar valley or Schwetzingen) with a large army, and defeated them with considerable loss on his own part. (Later, in 374, he made peace with their king, Macrianus.) The next three years he spent at Trier, which he chiefly made his headquarters, organizing the defence of the Rhine frontier.

During his reign the coasts of Gaul were harassed by the Saxon pirates, with whom the Picts and Scots of northern Britain joined hands, and ravaged the island from the wall of Antoninus to the shores of Kent. In 368 Theodosius was sent to drive back the invaders; in this he was completely successful, and established a new British province, called Valentia. In Africa the Moorish prince, Firmus, raised the standard of revolt against Count Romanus, the military governor. The services of Theodosius were again requisitioned. He landed in Africa with a small band of veterans, and Firmus, to avoid being taken prisoner, committed suicide. In 374 the Quadi, a German tribe in what is now Moravia and Hungary, resenting the erection of Roman forts to the north of the Danube, and further exasperated by the treacherous murder of their king, Gabinius, crossed the river and laid waste the province of Pannonia. The emperor, in April of the following year,

entered Illyricum with a powerful army, but during an audience to an embassy from the Quadi at Brigetio on the Danube (near Pressburg) died in a fit of apoplexy.

Valentinian's general administration seems to have been thoroughly honest and able, in some respects beneficent. If he was hard and exacting in the matter of taxes, he spent them in the defence and improvement of his dominions Though himself a plain and almost illiterate soldier, he was a founder of schools, and he also provided medical attendance for the poor of Rome, by appointing a physician for each of the fourteen districts of the city. He was an orthodox Catholic, but he permitted absolute religious freedom to all his subjects The great blot on his memory is his cruelty, which at times was frightful.

See Ammianus Marcellinus xxv.–xxx ; Gibbon, *Decline and Fall*, chap. 25; T. Hodgkin, *Italy and her Invaders*, bk i chap. 3, H. Richter, *Das weströmische Reich* (1865), pp. 240–268.

VALENTINIAN II., son of the above, an infant of four in 375 with his half-brother Gratian (*q.v.*) a lad of about seventeen, became the emperors of the West They made Milan their home; and the empire was nominally divided between them, Gratian taking the trans-Alpine provinces, whilst Italy, Illyricum in part, and Africa were to be under the rule of Valentinian, or rather of his mother, Justina In 387 Magnus Maximus (*q v.*), who had in 383 overthrown Gratian and made himself master of the northern provinces, crossed the Alps and threatened Milan The emperor and his mother fled to Theodosius, the emperor of the East. Valentinian was restored in 388 by Theodosius. Four years later he was murdered at Vienne in Gaul, probably at the instigation of his Frankish general Arbogast.

See Gibbon, *Decline and Fall*, chap 27; H. Richter, *Das weströmische Reich unter den Kaisern Gratian, Valentinian II. und Maximus* (1865), pp. 577–650, and O Seek, *Untergang des antiken Welt*, Vol. 5 (1897–1921).

VALENTINIAN III., emperor of the West from 425 to 455, the son of Constantius and Placidia. He was only six years of age when he ascended the throne, and during his minority the conduct of affairs was in the hands of his mother. His reign is marked by the dismemberment of the Western Empire; the conquest of the province of Africa by the Vandals in 439; the loss of great portions of Spain and Gaul, in which the barbarians had established themselves; and the ravaging of Sicily and of the western coasts of the Mediterranean by the fleets of Genseric. As a set-off against these calamities there was the great victory of Aetius over Attila in 451 near Châlons, and his successful campaigns against the Visigoths in southern Gaul (426, 429, 436), and against various invaders on the Rhine and Danube (428–31) Ravenna was Valentinian's usual residence; but he fled to Rome on the approach of Attila, who ravaged North Italy in 452. In 454 Aëtius was treacherously murdered by Valentinian. Next year, however, the emperor himself was assassinated by two of the barbarian followers of Aëtius. He was self-indulgent, incompetent, and vindictive.

Our chief original sources for the reign of Valentinian III. are Jordanes, Prosper's *Chronicles*, written in the 6th century, and the poet Apollinaris Sidonius. *See* also Gibbon, *Decline and Fall*, chaps. 33–35 and pp. 24 and 25 (ed London, 1909); J. B. Bury, *Later Roman Empire*, bk. ii. chaps. 6–8; E. A Freeman, "Tyrants of Britain, Gaul and Spain" (*Eng Hist. Review*, January 1886), and "Aetius and Boniface" (*ibid.*, July 1887).

VALENTINUS, pope for thirty or forty days in 827, in succession to Eugenius II. (824–27). He was a Roman by birth, and, according to the *Liber Pontificalis*, was first made a deacon by Paschal I. (817–24). Nothing further is known of his history, His successor was Gregory IV. (827–44).

VALENTINUS and **THE VALENTINIANS.** Valentinus, the most prominent leader of the Gnostic movement, was born, according to Epiphanius (*Haer.* 31, 2), near the coast in Lower Egypt, and was brought up and educated in Alexandria. Valentinus came to Rome (*c.* 135–160) during the episcopate of Hyginus, flourished under Pius and stayed till the time of Anicetus. According to Irenaeus iii. 3, 4, Polycarp, during his sojourn in Rome under the episcopate of Anicetus, converted a few adherents of the Valentinian sect. Tertullian (*Adv. Valentin.* cap. 4) declares that Valentinus came to Rome as an adherent of the orthodox Church, and was a candidate for the bishopric of Rome, but he abandoned the Church because a confessor was preferred to him for this office. The credibility of this statement may be questioned. Great uncertainty attaches to the residence of Valentinus in Cyprus, recorded by Epiphanius (*loc. cit.*), who places it after his stay in Rome, adding that it was here that he definitely accomplished his secession from the Church. But it seems to be clear that Valentinus did not, like Marcion, break with the Church from the very beginning, but endeavoured to maintain his standing within it

Justin's *Syntagma*, which treats of Valentinus, is unfortunately lost. Irenaeus, *Adversus Haereses*, i 11, 1–3, as in every other article where named, has preserved what is obviously an older document, possibly from Justin, dealing with Valentinus's own teaching and that of two of his disciples. The sketch which he gives is the best guide for the original form of Valentinianism. For Valentinus himself we have also to consider the fragments of his writings preserved by Clement of Alexandria. The best edition of and commentary on them is Hilgenfeld's *Ketzergeschichte des Urchristentums* (pp. 293–307). Irenaeus also gives a detailed account of the two chief schools following Valentinus, the school of Ptolemaeus (i. 1–10), and Marcus and the Marcosians (i 13–21). For his account of the Ptolemaeans, Irenaeus seems to have used various writings and expositions of the school, especially prominent being a collection of Scripture proofs which may have once had a separate literary existence (i. 1, 3; 3, 1–5 [6]; 8, 2–4). To this is appended in a somewhat disconnected fashion a commentary on the prologue to the fourth Gospel (i. 8, 5) Irenaeus himself twice prefaces his remarks by saying he is indebted to other authorities for his exposition (i. 2, 3–4; 7, 2–5). *Excerpta ex Theodoto* which are to be found in the works of Clement and may be looked upon as a collection made by the author with a view to the unfinished eighth book of his *Stromateis*. The lost *Syntagma* of Hippolytus, which can be partially reconstructed from Philaster (*Haereses*) and from pseudo-Tertullian (*Adversus Valentini anos*), seems to furnish us with valuable information as to the earlier doctrines of the sect; and in his second treatise against heretics, the so-called *Philosophumena* (6, 29 *seq.*), Hippolytus gives a homogeneous and continuous exposition of a later Valentinian system, possibly connected with the school of Ptolemaeus. Important, too, are Hippolytus' references to an Italic and an Anatolian branch of the Valentinian sect (6, 35). Tertullian gives at the beginning of his treatise against the Valentinians a few separate notices of the life and disciples of Valentinus, but his further argument is closely dependent upon Irenaeus' exposition of the Ptolemaean system, which he embellishes in his usual fashion with bitterly sarcastic comments. Epiphanius deals with Valentinus and his school in sections 31–36 of his work. He has preserved a valuable letter of Ptolemaeus to Flora, which is of the highest importance for the understanding of Gnosticism.

Valentinus is the only one of the Gnostics who had a whole series of disciples who are known by name—indeed, in the accounts of the Church Fathers his own system and views are almost entirely obscured by the accounts of those of his disciples. The most important disciples are the two dealt with at length by Irenaeus, Ptolemaeus and Marcus, who both seem to have had a numerous following. Also, there was Heraklcon, of whose commentary on the gospel of St. John extensive fragments are preserved by Origen. Ptolemaeus and Heraklcon are counted by Hippolytus (6, 35) among the Italic branch of Valentinianism There was also the Anatolian branch, as representative of which Hippolytus mentions Axionicus, who is also referred to by Tertullian as having actually been taught in Antioch. The *Excerpta ex Theodoto* in Clement are also, according to the superscription, fragments from the Anatolian Gnosticism. It is, however, an error when Hippolytus speaks of Bardesanes as representative of this branch, for he had an entirely distinct position. Valentinianism was based on primitive gnosticism (*q.v.*), with the doctrines of which Valentinus may have become acquainted in Egypt. The mother goddess stands at the centre of the system. The main doctrines are outlined below.

(1) Valentinus has a system of thirty aeons, but the quite shadowy plurality of ten and twelve aeons (the *Dekas* and the *Dodekas*) of the Valentinian system we may at once set aside as mere fantastical accretions. We have left only a group of eight celestial beings, the so-called Ogdoas, and of these eight figures four again are peculiar to this system.

(2) The first pair of aeons, *Bythos* and *Sige*, is an original innovation of the Valentinian school, and clearly betrays a monistic tendency. According to Irenaeus's account of the "Gnostics" (i. 29), their theory was that *Sophia* casts herself into the primal substratum of matter (*Bythos*) to be found outside the celestial world of aeons But in the Valentinian system matter is not originally and irretrievably separated from the higher celestial world, but the latter originally exists for itself alone; the fall or disturbance is accomplished within the celestial world, and the material world first comes into existence through the fall

(3) There remain a double pair of aeons, the Father and Truth, the *Anthropos* and the *Ekklesia*. With the celestial Primal Man—of whom the myth originally relates that he has sunk into matter and then raised himself up from it again—is associated the community of the faithful and the redeemed, who are to share the same fate with him

(4) In the true Valentinian system the so-called *Christos* is the son of the fallen Aeon, who is thus conceived as an individual. *Sophia*, who in a frenzy of love had sought to draw near to the unattainable *Bythos*, brings forth, through her longing for that higher being, an aeon who is higher and purer than herself, and at once rises into the celestial worlds Among the Gnostics of Irenaeus we find a kindred conception, but with a slight difference. Here *Christos* and *Sophia* appear as brother and sister, *Christos* representing the higher and *Sophia* the lower element. In the enigmatic figure of *Christos* we again find hidden the original conception of the Primal Man, who sinks down into matter but rises again. (In the later Valentinian systems this origin of the *Christos* is entirely obscured, and Christ, together with the Holy Spirit, becomes a later offspring of the celestial world of aeons; this may be looked upon as an approximation to the Christian dogma.)

(5) A figure entirely peculiar to Valentinian Gnosticism is that of *Horos* (the Limiter). The name is perhaps an echo of the Egyptian *Horus* The peculiar task of *Horos* is to separate the fallen aeons from the upper world of aeons He becomes a kind of world-creative power, who in this capacity helps to construct an ordered world out of *Sophia* and her passions. He is also called, curiously enough, *Stauros* (cross), and we frequently meet with references to the figure of *Stauros*. But we must not be in too great a hurry to assume that this is a Christian figure. A Platonic conception may have been at work here. The cross can also stand for the wondrous aeon on whom depends the ordering and life of the world, and thus *Horos-Stauros* appears here as the first redeemer of *Sophia* from her passions, and as the orderer of the creation of the world which now begins. The figure of *Horos-Stauros* was often assimilated to that of the Christian Redeemer

(6) The dualism of the two separate worlds of light and darkness was thus overcome. This derivation of the material world from the passions of the fallen *Sophia* is, however, affected by an older theory according to which the son of *Sophia*, whom she forms on the model of the *Christos* who has disappeared in the higher heavens, becomes the *Demiourgos*, who with his angels now appears as the real world-creative power. These two conceptions had now to be combined at all costs. And it is interesting to observe here what efforts were made to give the *Demiourgos* a better position. According to the older conception, he was an imperfect, ignorant, half-evil and malicious offspring of his mother, who has already been deprived of any particle of light (Irenaeus i. 29, 30). In the Valentinian systems he appears as the fruit of *Sophia's* repentance and conversion. He is no longer called *Jaldabaoth*, but has been assigned the better name, drawn from the philosophy of Plato, of *Demiourgos* The *Demiourgos* of the Gnostic corresponded to the God of the Old Testament, which again suggests a compromise with the Christian faith

(7) With the doctrine of the creation of the world is connected the subject of the creation of man. We fortunately know, from a fragment preserved by Clement, that Valentinus here preserved the old Gnostic myth practically unaltered in his system According to it, the world-creating angels—not one, but many—create man, but the seed of the spirit comes into their creature without their knowledge, by the agency of a higher celestial aeon, and they are then terrified by the faculty of speech by which their creature rises above them, and try to destroy him. A definite Valentinian idea is here added in that of the threefold nature of man, who is represented as at once spiritual, psychical and material. In accordance with this there also arise three classes of men, the *pneumatici*, the *psychici* and the *hylici* (ὕλη, matter) All the other Gnostic systems recognize only a dual division, the children of light and the children of darkness. That the Valentinians should have placed the *psychici* between the *pneumatics* and *hylici* signifies a certain recognition of the Christian Church and its adherents who are not treated as outcasts.

(8) At the centre of the whole Valentinian system naturally stands the idea of redemption, and so we find here developed particularly clearly the myth of the heavenly marriage already known from Irenaeus i 30 to be Gnostic. Redemption is essentially accomplished through the union of the heavenly *Soter* with the fallen *Sophia*. This myth of the redeemer is of significance for the practical piety of the Valentinian Gnostics. It is the chief idea of their pious practices mystically to repeat the experience of this celestial union of the *Soter* with *Sophia*. In this respect, consequently, the myth underwent yet wider development Just as the *Soter* is the bridegroom of *Sophia*, so the heavenly angels, who sometimes appear as the sons of the *Soter* and *Sophia*, sometimes as the escort of the *Soter*, are the males betrothed to the souls of the Gnostics, which are looked upon as feminine. Thus every Gnostic had his angel standing in the presence of God, and the object of a pious life was to bring about and experience this inner union with the celestial abstract personage This leads us straight to the sacramental ideas of this branch of Gnosticism.

(9) With this celestial *Soter* of the Valentinians and the redemption of *Sophia* is connected the figure of Jesus of Nazareth and the historical redemption connected with his name The *Soter*, the bridegroom of Sophia, and the earthly Jesus answer to each other as in some way identical. Here again we recognize the artificial compromise between Gnosticism and Christianity

(10) The Valentinians laid down that even the Redeemer has a threefold nature; from his mother, Sophia, he derived his nature as a *pneumaticos*, in the world of the Demiourgos he was united with the Christos, and finally a wonderful bodily nature was formed for him from celestial elements, which was yet not of earthly material As such he was miraculously born of the Virgin. The compromises with the Catholic Church are here obvious. Also, there was the idea that upon this Jesus, so constituted, yet another celestial nature, the Christos or the Soter, has descended at his baptism.

The first survey of these confused speculations, these myths gathered together and preserved from the ancient world, this marshalling together of the most varied traditions, and above all, these artificial attempts at compromise, makes us inclined to doubt whether it was possible for any true piety to coexist with all this. Yet such piety existed; indeed we have here a set of regular mystics. It is not, indeed, a purely spiritual and mystical piety, but a mysticism much distorted and over-grown with sacramental additions and a mysterious cult. But all this is not without an inner value and an attractive atmosphere. In a letter in Clement ii. 20, 114, Valentinus sets forth that the soul of man is like an inn, which is inhabited by many evil spirits "But when the Father, who alone is good, looks down and around him, then the soul is hallowed and lies in full light, and so he who has such a heart as this is to be called happy, for he shall behold God."

But with this mysticism is connected the mystery and cult of the sacrament. The lofty spirituality of the Gnostic degenerates over and over again into a distinctly material and sensual attitude, in which all kinds of efforts are made actually to assimilate to onesself the divine through external means.

The chief sacrament of the Valentinians seems to have been that of the bridal chamber. Just as the apostle Paul represented his Christianity as a living, dying and rising again with Christ, so the first concern of the pious Valentinian was the experience of the divine marriage feast of Sophia As Sophia was united with the Soter, her bridegroom, so the faithful would experience a union with their angel in heaven Through a fortunate chance, a liturgical formula which was used at this sacrament appears to be preserved It runs. "I will confer my favour upon thee, for the father of all sees thine angel ever before his face . we must now become as one; receive now this grace from me and through me; deck thyself as a bride who awaits her bridegroom, that thou mayest become as I am, and I as thou art Let the seed of light descend into thy bridal chamber; receive the bridegroom and give place to him, and open thine arms to embrace him. Behold, grace has descended upon thee."

Besides this the Gnostics already practised baptism, using the same form in all essentials as that of the Christian Church. The name given to baptism was *apolytrosis* (liberation) In one of the formulae occur the words "I would enjoy thy name, Saviour of Truth" The concluding formula of the baptismal ceremony is "Peace over all upon whom the Name rests" (Irenaeus 1 21, 3) This name pronounced at baptism over the faithful has above all the significance that the name will protect the soul in its ascent through the heavens, conduct it safely through all hostile powers to the lower heavens, and procure it access to Horos, who frightens back the lower souls by his magic word

Here and there a reaction took place against the absurdity of this sacramental superstition Thus Irenaeus (i 21, 4) tells us of certain Gnostics who would admit no external holy practices as efficacious A pure piety breathes in the words of the Gnostics preserved in *excerpta ex Theodoto*, 78, 2: "But not baptism alone sets us free, but knowledge (*gnosis*): who we were, what we have become, where we were, whither we have sunk, whither we hasten, whence we are redeemed, what is birth and what rebirth"

We have seen that Valentinian Gnosticism affected the nearest approach of all the Gnostic sects to the Catholic Church Valentinus's own life indicates that he for a long time sought to remain within the official Church, and had at first no idea of founding a community of his own

And yet this reconciliation of Gnosticism was a fruitless and henceforward a purposeless undertaking Oriental dualism and wildly intemperate Oriental mythology had grown into so radical and essential a part of Gnosticism that they could not be separated from it to make way for a purer and more spiritual view of religion And at a time when the prevailing tendency of Christianity was a struggle out of the darkness of Oriental mythology and eschatology into clearness, and an effort towards union with the lucid simplicity of the Hellenic spirit, these Gnostics, for all their efforts, and even the most noble of them, had come too late They are not the men of a forward movement, but they are, and remain, in spite of all clearer insight, the rear-guard of piety.

VALENZUELA, FERNANDO DE (1630–1692), Spanish royal favourite and minister, was born at Naples on Jan. 19, 1630 He obtained a footing in the palace by his marriage with Maria de Uceda, lady-in-waiting to Mariana, Philip IV.'s second wife. When he was appointed introducer of ambassadors (Oct. 12, 1671), it became notorious that whoever had a petition to present must apply to him. He became popularly known as the *duende*, the fairy or brownie of the palace, and was believed to be the lover of the queen Dismissed (1675) from court by intrigue, he was made marquis of Villa Sierra by the queen and ambassador to Venice He exchanged the embassy for the governorship of Granada, organized a counter-intrigue and returned to court. The queen-regent appointed him prime-minister and made him a grandee, to the profound indignation of the other grandees At the palace revolution of Jan. 1678, Valenzuela fled to the Escorial, was captured, degraded from the grandeeship, exiled to the Philippines and his property confiscated. He died in Mexico on Feb 7, 1692

See *Documentos inéditos para la Historia de España*, vol. lxvii. (1842, etc).

VALERA Y ALCALÁ GALIANO, JUAN (1824–1905), Spanish novelist, entered diplomacy in 1847 and became unpaid attaché to the Spanish embassy at Naples under the famous duke de Rivas He held various other diplomatic posts until 1858 when he returned to Spain and entered the House of Deputies, taking his place with the Liberal opposition On the flight of Isabella II. in 1868 he was elected deputy for Montilla in the province of Cordova, became under-secretary of state for foreign affairs, and was one of the deputation who offered the crown to Amadeus of Savoy in the Pitti Palace at Florence. Though he always called himself a Moderate Liberal, Valera invariably voted for what are considered Radical measures in Spain, and a speech delivered by him in Feb 1863 against the temporal power of the pope created a profound sensation. However, though a member of the revolutionary party, he steadily opposed organic constitutional changes, and therefore he retired from public life during the period of republican government After the Bourbon restoration he acted as minister at Lisbon (1881–83), at Washington (1885), at Brussels (1886) and as ambassador at Vienna (1893–95), retiring from the diplomatic service on March 5, 1896 During his last ten years he took no active part in politics.

Valera's *Poesías* (1858) are imitative exercises rather than original poetry His criticism in the *Estudios críticos sobre literatura* (1864), in the *Disertaciones y juicios literarios* (1878) and in the *Nuevos estudios críticos* (1888) show penetration and taste, but also an excessive amiability. He said a hundred incisive, wise, witty, subtle and suggestive things concerning the mysticism of St Theresa, the art of novel-writing, *Faust*, the Inquisition, *Don Quixote*, Shakespeare, the psychology of love in literature; but, to do himself justice, it was an almost indispensable condition that he should deal with the past. In the presence of a living author Valera was disarmed

When in his 50th year, he published *Pepita Jiménez* (1874) a recital of the fall of Luis de Vargas, a seminarist who conceived himself to be a mystic and a potential saint, and whose aspirations dissolve at the first contact with reality It is easy to point out blemishes the story is not well constructed, and it has pauses during which the writer's fantasy plays at pleasure over a hundred subjects not very germane to the matter; but its characters are as real as any in fiction, the love story is told with the most refined subtlety and malicious truth, while page upon page is written in such Spanish as would do credit to the best writers of the 16th and 17th centuries. A second novel, *Las ilusiones del Doctor Faustino* (1875), was received with marked disfavour, and has the faults of over-refinement and of cruelty, yet in keen analysis and in humour it surpasses *Pepita Jiménez* The *Comendador Mendoza* (1877) is more pathetic and of a profounder significance, and in *Doña Luz* (1879) repeats the situation and the general ides already used in *Pepita Jiménez* it strikes a deeper and more tragic note, which came as a surprise to those familiar only with the lighter side of Valera's genius. Besides these elaborate psychological studies, Valera issued a volume of *Cuentos* (1887), some of these short tales and dialogues being marvels of art and of insight.

At the close of the 19th century Valera was recognized as the most eminent man of letters in Spain. He had not Pereda's force nor his energetic realism; he had not the copious invention nor the reforming purpose of Pérez Galdós; yet he was as realistic as the former and as innovating as the latter. And, for all his cosmopolitan spirit, he fortunately remained intensely and incorrigibly Spanish. His aristocratic scepticism, his strange elusiveness, his incomparable charm are his own; his humour, his flashing irony, his urbanity are eminently the gifts of his land and race. He is by no means an impersonal artist; in almost every story there is at least one character who talks and thinks

and subtilizes and refines as Valera himself, wrote in his most brilliant essays This may be a fault in art, but, if so, it is a fault which many great artists have committed (J.F.-K.)

VALERIA, VIA, an ancient highroad of Italy, the continuation north-eastwards of the Via Tiburtina (*q.v.*). It probably owed its origin to M. Valerius Messalla, censor in 154 B.C. It ran first up the Anio valley past Varia (*q.v.*), and then, abandoning it at the 36th mile, where the Via Sublacensis diverged, ascended to Carsioli (*q.v.*), and then again to the lofty pass of Monte Bove (4,003 ft.), whence it descended again to the valley occupied by the Lago di Fucino (*q.v.*). The difficult route from Cerfennia, the easternmost point of Marsian territory, to the valley of the Aternus (mod. Pescara)—a drop of nearly 1,000 ft., involving too the crossing of the main ridge of the Apennines (3,675 ft.) by the Mons Imeus (mod. Forca Caruso)—was not made into a highroad until the reign of Claudius, who also constructed a road, the Via Claudia Nova, connecting the Via Salaria, which it left at Foruli (mod. Civitatomassa, near Amiternum) with the Via Valeria near the modern Popoli. This road was continued south to Aesernia From Popoli the road followed the valley of the Aternus to its mouth, and there joined the coast-road at Pescara The modern railway from Rome to Castellammare Adriatico follows closely the line of the Via Valeria.

See R. Gardner in *Papers of the British School at Rome*, ix., 75–106.

VALERIAN, a genus of herbaceous perennial plants of the natural order Valerianaceae. Two species—*Valeriana officinalis* and *V. dioica*—are indigenous in Britain, while a third, *V. pyrenaica*, is naturalized in some parts. The valerians have opposite leaves and small flowers, usually white or reddish, and arranged in terminal cymes. The limb of the calyx is remarkable for being at first inrolled and afterwards expanding in the form of a feathery pappus which aids in the dissemination of the fruit. The genus comprises about 150 species, which are widely distributed in the temperate parts of the world. In medicine the root of *V officinalis* is intended when valerian is mentioned

Valerian is cultivated in England, but to a much greater extent in Saxony, in Holland and in the United States The dried root or rhizome consists of a short central erect portion, about the thickness of the little finger, surrounded by numerous rootlets about $\frac{1}{16}$ of an inch in diameter, the whole being of a dull brown colour. When first taken from the ground it has no distinctive smell; but on drying it acquires a powerful odour of valerianic acid. This odour, now regarded as intolerable, was in the 16th century considered to be fragrant, the root being placed among clothes as a perfume (Turner, *Herbal*, 1568, part iii. p. 76), just as *V. celtica* and other species are still used in the East.

VALERIAN (VALERIANA OFFICINALIS), ONE-THIRD NATURAL SIZE
A, flower; B, flower after removal of corolla; C, fruit crowned by the feathery pappus (A, B, & C enlarged)

The red valerian of gardens is *Centranthus ruber*, also belonging to the Valerianaceae; but Greek valerian is *Polemonium coeruleum*, belonging to the family Polemoniaceae Cats are nearly as fond of the smell of this plant as of the true valerian, and will frequently roll on the plant and injure it.

The chief constituent of valerian is a volatile oil, which is present in the dried root to the extent of 1–2%, plants growing on dry or stony soil being said to yield the largest quantity. The oil is of complex composition, containing valerianic (valeric), formic and acetic acids combined with a terpene, $C_{10}H_{16}$; the alcohol known as borneol; and pinene Valerian acts medicinally entirely in virtue of its volatile oil, which exerts the actions typical of its class. The special use of this drug, like that of others which contain an offensive volatile oil—such as asafoetida—is in hysteria from A.D. 253 to 260. He was of noble family, and in 238 was *princeps senatus*. In 251, when Decius revived the censorship with practically supreme civil authority, Valerian filled the post. Gallus, the successor of Decius, summoned him from the upper Rhine in 253 when threatened by the rebellion of Aemilianus The soldiers, however, proclaimed Valerian emperor, and marching slowly towards Rome he found both his rivals dead, slain by their own soldiers Trouble on the frontiers east and west was complicated by something near national bankruptcy. Valerian left his son, Gallienus, in charge of the wars in Europe; and took the offensive against the Goths, recaptured Antioch and marched to relieve Edessa. He was defeated and taken prisoner, and disappears from history (258)

See Trebellius Pollio, *Life of Valerian* (frags.); Aurelius Victor, *Caesares*, 32, Eutropius ix 6; Ammianus Marcellinus xxiii. 5; Zosimus i 27; Gibbon, *Decline and Fall*, chap. 10; H. Schiller, *Geschichte der römischen Kaiserzeit* (1883–86) i pt. 2.

VALERIC ACID or **VALERIANIC ACID,** an organic acid belonging to the fatty acid series ($C_nH_{2n+1}CO_2H$). It exists in four different forms, all having the same formula, $C_4H_9.CO_2H$ (*See* ISOMERISM.) One of these contains an asymmetric carbon atom and consequently occurs in two optically active modifications and one optically inactive modification. Ordinary valeric acid (baldrianic acid) is a mixture of *iso*valeric acid or *iso*propylacetic acid $(CH_3)_2CH.CH_2.CO_2H$, and optically active methylethylacetic acid $(CH_3)(C_2H_5)CH.CO_2H$, both of which occur free or as esters in the vegetable and animal kingdoms, chiefly in the roots of *Angelica archangelica* and *Valeriana officinalis*. It may be extracted by boiling with water or soda. A similar product is obtained by oxidizing fermentation amyl alcohol with chromic acid. Isovaleric acid is an oily liquid having the odour of stale cheese and boiling at 174° C; its salts are usually greasy to the touch Potassium permanganate oxidizes it to *β* hydroxisovaleric acid $(CH_3)_2C(OH).CH_2.CO_2H$, whilst nitric acid gives, among other products, dinitropropane, $(CH_3)_2C(NO_2)_2$. The acid has been synthesized, as has also the inactive form of methylethylacetic acid; this modification is split into its optical antipodes by crystallization of its brucine salt Normal valeric acid or propylacetic acid, $CH_3.CH_2.CH_2.CO_2H$, is a liquid boiling at 186°. The remaining isomeride, pivalic or trimethylacetic acid, $(CH_3)_3C.CO_2H$, melts at 35° and boils at 163°; it is prepared by oxidizing pinacolin. (*See* KETONES.)

VALERIUS FLACCUS, GAIUS, Roman poet, flourished under Vespasian and Titus. He has been identified on insufficient grounds with a poet friend of Martial (i. 61. 76), a native of Padua. His work, the *Argonautica*, dedicated to Vespasian on his setting out for Britain, was written during the siege, or shortly after the capture of Jerusalem by Titus (70) It is an epic in eight books on the Quest of the Golden Fleece and is not wholly extant. Part is borrowed from Apollonius of Rhodes.

The *Argonautica* was unknown till the first four and a half books were discovered by Poggio at St Gall in 1417. The *editio princeps* was published at Bologna (1474) Recent editions by G. Thilo (1863), with critical notes, C. Schenkl (1871), with bibliography; E. Baehrens (1875), with critical introduction, P. Langen (1896), with Latin notes, and short introductions on the style and language, Caesar Giarratano (1904); *see* also J. Peters, *De V. F. Vita et Carmine* (1890); W. C. Summers, *Study of the Argonautica* (1894).

VALERIUS MAXIMUS, Latin writer, flourished in the reign of Tiberius. His family was poor, and he owed everything to Sextus Pompeius (consul A.D. 14), proconsul of Asia and a kind of minor Maecenas, whom he accompanied to the East in 27. He intimates that his work is intended as a commonplace book of historical anecdotes for use in the schools of rhetoric. The stories are loosely and irregularly arranged, and are from Roman history, but each section includes extracts from the annals of other peoples, principally the Greeks. The work reproduces the general feeling of the empire, that the Romans of the day are degenerate compared with their ancestors, but still vastly superior to the rest of the world

The author's chief sources are Cicero, Livy, Sallust and Pom-

peius Trogus In spite of his confusions, contradictions and anachronisms, the excerpts are apt illustrations Valerius often used sources now lost, and affords us some glimpses of the much debated and very imperfectly recorded reign of Tiberius Modern criticism will hardly regard as flattery his description of Tiberius, once so misunderstood, as *salutaris princeps*. He reveals the transition from classical to silver Latin It is an instructive lesson to compare minutely a passage of Valerius with its counterpart in Cicero or Livy The tenth book of the ms., the *Liber de Praenominibus*, is much later. The collection was used as a schoolbook, and was very popular in the middle ages.

One complete epitome, probably of the 4th or 5th century, bearing the name of Julius Paris, has come down to us, also a portion of another by Januarius Nepotianus. Editions by C. Halm (1865) and C Kempf (1888), contain the epitomes of Paris and Nepotianus.

VALÉRY, PAUL (1871–1945), French poet, was born at Cette on Oct 30, 1871 He first became known as the author of several apocalyptic poems of remarkable beauty and form, which appeared in such reviews as *L'Ermitage*, *Le Centaure*, etc., and were issued later in a collection entitled *Album de Vers anciens* (1920). From 1900 to 1917 Valéry lived in strict retirement and published nothing. During this period, however, his ideas matured, and he accumulated material later given to the public in *Cahier B, Rhumbs* and *Analecta*. It was not until 1917 that he published his first great poem *La Jeune Parque*, dedicated to André Gide. Then came *Aurore* (1917), *Le Cimitière marin* (1920), *La Platane*, *L'Ebauche d'un Serpent*, etc., which appeared in a collection entitled *Les Charmes* (1922). Valéry also wrote critical essays (on Stendhal, Poe, etc.) and philosophical treatises (*Introduction à la méthode de Léonard de Vinci*, *Soirée avec M. Teste*) of which some were collected under the title *Variétés* (1924), *Eupalinos* and *Ame et la Danse* (1923), two Platonic dialogues.

Valéry initiated a new movement in French poetry Influenced by Mallarmé, especially in his sense of verbal music, he believed with the symbolists that pure poetry must have value in itself apart from any reference to the accidents of being. Interested in philosophy and mathematics, he was a poet-mathematician trying to set his subtle analysis to music Valéry was a member of the Académie française from 1926. He died July 20, 1945, at Paris.

See H A L Fisher, *Paul Valéry* (1927); R. Fernandat, *P. Valéry* (1927); F. Souday, *P. Valéry* (1927); *Hommage des écrivains étrangers à Paul Valéry* (Maestricht, 1928), containing appreciations by R. M Rilke, R. Kayser, T. Shuge Moon, P Zaffer, È Cecchi, and others.

VALHALLA, according to the heathen Scandinavians the abode where the souls of those who had fallen in battle (Old Norse *Valhöll*, *i.e.*, "hall of the slain") are received by the god Odin, and fight and feast in his service. (*See* TEUTONIC PEOPLES.)

VALJEVO, a town in western Serbia, Yugoslavia, lying in a pine clad valley 627 ft. above sea level. Pop. (1931) 11,055. Besides being the centre of the plum growing and distillery industries, Valjevo has a considerable trade in cattle, the pastures watered by the Kolubra being famous. The best nut trees in Serbia flourish here. It was at Valjevo that the standard of revolt against the Turks was raised in 1804, and during the second rising in 1815 Prince Milosh captured the town.

During the Balkan campaign of World War II, Valjevo was occupied by German troops advancing westward from Rumania and Bulgaria, shortly after the fall of Belgrade in April 1941.

VALKYRIES, generally represented in Northern mythology as divine maidens who, sent by Odin, ride through the air to determine the course of battles and to select brave warriors for Valhalla (*q.v.*). Beings with the same name (*waelcyrgean*) were in England associated with witches.

VALLA, LORENZO or **LAURENTIUS** (*c.* 1407–1457), Italian humanist, was born at Rome about 1406, his father, Luca delle Vallea, being an advocate He was educated at Rome, became a priest in 1431, and wandered from one university to another lecturing. About 1437 he became private secretary to Alphonso V of Aragon, who ever afterwards protected him, and later helped him to open a school at Naples Valla by now had achieved a great reputation by the *De Voluptate* and the *De Elegantus Linguae Latinae* The first is a remarkable dialogue presenting in turn the Stoic, Epicurean and Christian ethical systems Christianity is allowed to prevail, but Epicurus is very favourably treated The *De Elegantus* is a scientific analysis of the rules of Latin grammar and style In 1444 he appeared his famous exposure of the Donation of Constantine (*q.v.*), followed by other attacks on spurious documents He was compelled to appear before an inquisitory tribunal composed of his enemies, and he escaped only by the special intervention of Alphonso He was not, however, silenced; he ridiculed the Latin of the Vulgate and accused St Augustine of heresy In 1446 he visited Rome, but in this city also his enemies were numerous and powerful, and he saved his life only by flying in disguise to Barcelona, whence he returned to Naples. After the death of Eugenius IV in 1447 he went again to Rome, where he was welcomed by the new pope, Nicholas V, who made him an apostolic secretary, and this entrance of Valla into the Roman Curia has been justly called "the triumph of humanism over orthodoxy and tradition." Valla also enjoyed the favour of Pope Calixtus III. His most famous dispute was with Poggio (*q.v.*). He died in Rome on Aug 1, 1457.

Over Valla's private life, the most obscene language was employed. He appears as a vain, jealous and quarrelsome man, but an elegant humanist, an acute critic and a venomous writer, who had committed himself to a violent polemic against the temporal power of Rome. In him posterity honours the man who initiated a bold criticism, which he applied to language, to historical documents and to ethical opinions. Luther had a high opinion of him, and Cardinal Bellarmine calls him *praecursor Luthers*, while Sir Richard Jebb says that his *De Elegantus* "marked the highest level that had yet been reached in the critical study of Latin."

Collected, but not quite complete, editions of Valla's works were published at Basle in 1540 and at Venice in 1592 *seq.*, and *De Elegantis* was reprinted nearly 60 times between 1471 and 1536. For detailed accounts of Valla's life and work *see* G. Voigt, *Die Wiederbelebung des classischen Alterthums* (1880–81); J. A. Symonds, *Renaissance in Italy* (1897–99), G Mancini, *Vita di Lorenzo Valla* (Florence, 1891); M von Wolff, *Lorenzo Valla* (Leipzig, 1893); J Burckhardt, *Kultur der Renaissance* (1860); J Vahlen, *Laurentius Valla* (1870); L Pastor, *Geschichte der Papste*, Band ii. Eng. trans by F. I Antrobus (1892); the article in Herzog-Hauck's *Realencyklopadie*, Band xx. (Leipzig, 1908); J. E Sandys, *Hist of Class Schol.* ii. (1908), pp. 66–70; and V. Rossi, *Il Quatrocento*, and ed. (Milan, 1933)

VALLABHACHARS, a numerous sect in western and central India in which the emotional and erotic elements are allowed free scope, aided by vernacular dialects in prayers and hymns of praise.

Vallabha, the son of a Telinga Brahman, lived at Gokula near Mathura, and set up a shrine with an image of Krishna Gopala. Vallabha went subsequently to reside at Benares, where he died. In the doctrine of this Vaishnava prophet, if the human soul is identical with God, the practice of austerities must be discarded as directed against God, and it is rather by a free indulgence of the natural appetites and the pleasures of life that man's love for God will best be shown. The followers of this creed direct their worship chiefly to Gopal Lal, the boyish Krishna of Vrindavana, whose image is sedulously attended like a revered living person eight times a day—from its early rising from its couch to its retiring to repose at night. The sectarial mark of the adherents consists of two red perpendicular lines, meeting in a semicircle at the root of the nose, and having a round red spot painted between them. Their principal doctrinal authority is the Bhagavata-purana, as commented upon by Vallabha himself, the author of several other Sanskrit works highly esteemed by his followers Children are solemnly admitted to full membership at the early age of four, and even two years, when a rosary, or necklace, of 108 beads of basil (tulsi) wood is passed round their necks, and they are taught the use of the octo-syllabic formula *Sri-Krishnah saranam mama*, "Holy Krishna is my refuge." Their spiritual heads, the Gosains, also called Maharajas, adorn themselves in splendid garments, and allow themselves to be habitually regaled by their adherents with choice kinds of food; and as the living representatives of the "lord of the Gopis" himself, claim and receive in their own persons all acts of attachment

and worship due to the deity, even, it is alleged, to the extent of complete self-surrender. In the final judgment of the famous libel case of the Bombay Maharajas, before the Supreme Court of Bombay, in January 1862, these improprieties were severely commented upon.

A modern offshoot of Vallabha's creed, formed with the avowed object of purging it of its objectionable features, was started, in the early years of the 19th century, by Sahajananda, a Brahman of the Oudh country, who subsequently assumed the name of Svami Narayana Having entered on his missionary labours at Ahmadabad, and afterwards removed to Jetalpur, where he had a meeting with Bishop Heber, he subsequently settled at the village of Wartal, to the north-west of Baroda, and erected a temple to Lakshmi-Narayana, which, with another at Ahmadabad, form the two chief centres of the sect, each being presided over by a Maharaja.

VALLADOLID, a town of Mexico in N E Yucatán Pop. (est 1950) 7,000 Founded 1544 on an ancient Maya site (Zaci), Valladolid lies in a fertile, healthful section and is famous as an ancient ecclesiastical centre and health resort. Numerous native uprisings, notably the War of the Castes (1847–53), destroyed many of its colonial edifices. It is the commercial hub of its area. (HD C.)

VALLADOLID, an inland province of Spain, one of the eight into which Old Castile was divided in 1833. Population (1950 census) 340,915, area, 3,155 sq mi

The province belongs to the basin of the river Duero (Douro) It is for the most part flat and exceedingly fertile, the only part that can be called hilly being in the northwest, where the low Montes de Torozos occur Valladolid shares with the Tierra de Campos in Palencia the title of granary of the Peninsula

Besides wheat, maize, barley and oats, the province produces hemp, flax, various fruits, red and white wine, oil and madder. Honey, wax and silk are also produced. The woollen fabrics of Valladolid were once highly esteemed, but this industry later greatly declined, although in the larger towns there are still linen and cloth factories, besides iron foundries, tanneries, saw-mills and flour-mills Trade is facilitated by the Canal de Castilla, connecting Valladolid, on the Pisuerga, with Alar del Rey, in Palencia. Valladolid is traversed from north to south by the railway from Madrid to France. Apart from the capital Valladolid (*q v.*), Medina del Campo (13,242) is the only large town The province was captured by nationalist troops in 1936, during the early stages of the civil war of 1936–39

VALLADOLID, the capital of the Spanish province of Valladolid, 2,228 ft above sea-level, at the confluence of the river Pisuerga with the Esgueva Pop (1940) 120,000 (mun, 124,212). It is sometimes identified with the ancient Pintia of Ptolemy. Its Roman origin is uncertain. The present name is undoubtedly Moorish Valladolid was recovered from the Moors in the 10th century, but is first named by Sancho II of León in 1072 The cortes of Castile frequently met here in the following centuries, and in the beginning of the 15th century John II made it his principal residence After the removal of the capital to Madrid by Philip II in 1560 it began rapidly to decay Columbus died (1506) and Philip II was born (1527) at Valladolid.

Valladolid is an archbishopric, and the seat of an army corps, a court of appeal and a university. It is connected by numerous railways with every province of Spain. The granite cathedral was begun in 1585 by Juan de Herrera in the Renaissance style. The interior contains pictures by Luca Giordano (1632–1705) and the celebrated silver monstrance wrought by Juan de Arphe. Other buildings are the church of Santa Maria la Antigua (1200); the church of San Pablo (1286); San Gregorio (15th century); and San Benito (end of the 14th century). The Plateresque college of Santa Cruz, built by Enrique de Egas in 1479–92, contains three pictures by Rubens, and some remarkable wooden statues by Alonso Berruguete (d. 1581), Gregorio Hernandez (1566–1636) and others. The university, originally founded at Palencia early in the 13th century, was transferred to Valladolid before 1250. The house in which Cervantes lived (1603–6) has been preserved by the Hispanic Society of America. The principal industries are the manufacture of linen, silk and woollen fabrics, pottery, gold and silver work, flour, wine, beer, chocolate, leather, ironware

VALLANDIGHAM, CLEMENT LAIRD (1820–1871), American politician, was born in New Lisbon, Ohio, on July 29, 1820 He was duly admitted to the bar in 1842. Elected to the Ohio house of representatives in 1845, he became one of the extremists of the state rights Democrats of his section From 1858 to 1863 he was in the lower house of Congress, where he was noted for his strong opposition to the principles and policies of the growing Republican party, his belief that the South had been grievously wronged by the North, his leadership of the peace democrats or "copperheads," who were opposed to the prosecution of the war, and his bitter attacks upon the Lincoln administration, which, he said, was destroying the Constitution and would end by destroying civil liberty in the North In 1863 he made violent speeches in Ohio against the administration, and for these he was arrested by the military authorities, tried by military commission, and sentenced to imprisonment President Lincoln commuted this sentence to banishment, and Vallandigham was sent into the Confederate lines, whence he made his way to Canada. While in exile he was elected supreme commander of the Knights of the Golden Circle in Ohio and received the Democratic nomination for governor of Ohio, but was defeated In 1864 he returned to Ohio, took active part in the campaign of that year, wrote part of the national Democratic platform at Chicago, and assisted to nominate McClellan for the presidency After the war he denounced the reconstruction policy of the Republicans as unconstitutional and tyrannical, but in 1870, seeing the uselessness of further opposition, he advised his party to accept the situation and adopt new issues. Vallandigham was an able lawyer and a popular politician. He died in Lebanon, Ohio, on June 17, 1871.

See J L Vallandigham, *Life of Clement L. Vallandigham* (Baltimore, 1872), J. F Rhodes, *History of the United States from the Compromise of 1850* (1839–1906); H van Fossan, "Clement L. Vallandigham," in *Ohio Archaeological and Historical Quarterly*, vol. xxiii., p. 256–267 (1914).

VALLE, PIETRO DELLA (1586–1652), Italian traveller in the East, came of a noble Roman family, and was born on April 11, 1586, in the family palace built by Cardinal Andrea. He served against the Moors of Barbary, but also became a member of the Roman academy of the Umoristi, and acquired some reputation as a versifier and rhetorician The idea of travelling in the East was suggested by a disappointment in love, as an alternative to suicide, and was ripened to a fixed purpose by a visit to the learned Mario Schipano, professor of medicine in Naples, to whom the record of Pietro's travels was addressed in the form of very elaborate letters, based on a full diary. Before leaving Naples he took a vow of pilgrimage to the Holy Land, and, sailing from Venice in 1614, reached Constantinople, where he remained for more than a year, and acquired a good knowledge of Turkish and a little Arabic. In September 1615 he sailed for Alexandria with a suite of nine persons. From Alexandria he went on to Cairo, and, after an excursion to Mount Sinai, left Cairo for the Holy Land in March 1616, in time to assist at the Easter celebrations at Jerusalem. Having visited the holy sites, he journeyed by Damascus to Aleppo, and thence to Baghdad, where he married a Syrian Christian named Maani, a native of Mardin, who died in 1621 He now desired to visit Persia; but, as that country was then at war with Turkey, he had to leave Baghdad by stealth in Jan 1617. Accompanied by his wife he proceeded by Hamadan to Isfahan, and joined Shah Abbas in a campaign in northern Persia, in the summer of 1618. Here he was well received at court. On his return to Isfahan he began to think of returning by India rather than Turkey; but the state of his health and the war between Persia [illegible]

[illegible]

reached Rome on March 28, 1626, and was received with much

honour by Pope Urban VIII, who appointed him a gentleman of his bedchamber. He died at Rome on April 21, 1652.

VALLE-INCLÁN, RAMON DEL (1869–1936), Spanish novelist and poet, was born at Puebla de Caramiñal (Pontevedra) A subtle artificer in his verse—*Aromas de leyenda* (1907), *Cuento de Abril* (1910), *Cara de plata* (1923)—he writes a refined and delicate prose in the *Memorias del marqués de Bradomín* (*Sonatas de primavera, de estío, de otoño* and *de invierno* [1902–1907]), while his *Guerra Carlista* is an impressive historical work.

VALLEJO, a city of Solano county, California, U.S.A., on San Pablo bay at the mouth of the Napa river, 25 mi. N.E. of San Francisco. It is served by the Southern Pacific railroad, passenger bus lines and by steamships for coastal as well as foreign trade.

The population of Vallejo was 26,038 in 1950 and was 20,072 in 1940 by the federal census.

Across Mare Island straits are the Mare Island naval shipyard and other naval establishments, making this the largest naval installation on the west coast. Vallejo was settled about 1849. It was named after Gen. Mariano Guadalupe Vallejo, a prominent Mexican leader. Through his efforts it became the state capital for a brief period, and the legislature met there in 1851, 1852 and 1853. In the struggle for the terminus of the Central Pacific railway (1869–72) it was a formidable, though unsuccessful, rival of Oakland.

VALLÈS, JULES (1832–1885), French journalist and author, was born at Puys, France, on June 10, 1832. Coming to Paris, he joined the staff of the *Figaro* and became a constant contributor to the other leading journals. He was in Paris during the siege of 1870 and after the capitulation was a member of the Commune and founded *Le Cri du Peuple*. He took a conspicuous part in the fighting in the Paris streets but finally made his escape to London, whence he contributed anonymously to the French press.

In 1878 he began in the *Siècle* the serial publication of his principal work, *Jacques Vingtras*, a long autobiographical romance. He died in Paris on Feb. 14, 1885.

VALLETTA or **VALETTA**, the capital of Malta (since 1570). Pop. (1946) 18,666. The nucleus of the city is built on a ridge of rock (Mount Sceberras) which runs like a tongue into the middle of a bay, which it thus divides into two harbours, the Grand harbour to the east and the Marsamuschetto to the west, which are subdivided again by three other peninsulas into creeks. On two of these peninsulas on the east side of the Grand harbour, and at their base, are built the aggregate of towns called the Three Cities—Vittoriosa, Conspicua and Senglea. (*See* MALTA.) On the main promontory, with Valletta, stands the suburb Floriana; Fort St. Elmo, with a lighthouse, stands on the extremity of the promontory; the suburb Sliema lies on the point which encloses the Marsamuschetto harbour; Fort Ricasoli is on the opposite point, enclosing the east, Grand, or Great harbour. The streets of Valletta, paved with stone, run along and across the ridge and end on each side toward the water in steep flights of steps. At the start of World War II the city contained several fine public buildings, as the Grand Master's palace (official residence of the governor), the Royal Opera house, the Royal Malta library (having 200,000 vol. and 1,185 MSS.), the Museum of Maltese antiquities and the *auberges* or lodges of the Knights of Malta (especially the Auberge de Castile et Leon), these last used for military offices, clubrooms and other purposes. Roman Catholic churches in Valletta were very numerous; the cathedral of S. Giovanni, dating from 1576, was famous for its rich inlaid marbles, its Brussels tapestries, its roof painted by Matteo Preti (1661–99), a picture by Michelangelo da Caravaggio of the beheading of John the Baptist and numerous memorials of the knights and other relics. All these magnificent memorials of the past suffered irreparable damage during World War II, the majority of them being completely destroyed. Valletta was the principal objective of unparalleled bombing raids on Malta by both Italian and German aircraft, which commenced on June 11, 1940, and continued for nearly three years on a scale unequalled elsewhere in the world.

After the British occupation Valletta became a naval and military station of the first importance. The naval dockyard and victualling stores occupied the shores of the two main creeks within the great harbour. The large transit trade and the local trade of the island also centred in the city.

See Ian Hay, *The Unconquered Isle* (1943).

VALLEY CITY, a city of North Dakota, U.S.A., on federal highway 10. Pop (1950) 6,851. It is the seat of a state teachers' college (established 1890). It was incorporated in 1881.

VALLEYFIELD (Salaberry-de-), city and port of entry, Beauharnois county, Quebec, Canada, 25 mi. S.W. of Montreal, at the foot of Lake St. Francis—an expansion of the river St. Lawrence—and at the head of the old and the new Beauharnois canals. Pop. (1951) 22,414. It is the see of a Roman Catholic bishop, and contains a college and normal school. Industries include cotton and silk mills, flour mills and chemical works.

VALLEY FORGE, an area about 20 mi. northwest of Philadelphia, Pa, U.S.A, where the American Revolutionary army of about 11,000 men under George Washington spent the winter of 1777–78. Their sufferings there from cold, starvation and sickness hallowed the historic site for Americans. The troops wintered in log huts and received little food or clothing. On Dec. 23, 1777, Washington wrote: "We have this day no less than 2,873 men in camp unfit for duty because they are barefooted and otherwise naked. . . . Numbers are still obliged to sit all night by fires" There were many desertions and occasional symptoms of mutiny, but for the most part the soldiers bore their sufferings with heroic fortitude. In Feb. 1778 the winter encampment became the first training camp of any United States armed forces. Under the drillmaster, Baron Frederick von Steuben, the army was reorganized, and left Valley Forge June 19, 1778, an efficient fighting unit. Of the original encampment 2,033 ac. is owned, maintained and preserved by the commonwealth of Pennsylvania and known nationally as Valley Forge park. Washington headquarters, Varnum quarters, Commissary quarters and much of the military works used by the Continental army are restored. The ruins of the valley forge, an iron plant which gave name to the area, and which the British burned in Sept. 1777, have been excavated. Statues of Anthony Wayne and Von Steuben and the National Memorial Arch, erected as a tribute to all the men, are outstanding monuments. The locations of troop units from each of the 13 original Colonies are indicated by granite markers. One memorial to Washington is the magnificent Washington Memorial chapel with its national carillon of 49 bells, one for each state and one for the union.

(G. S. J.)

VALLEY OF TEN THOUSAND SMOKES, a volcanic region in Alaska, which came into being at the time of the eruption of Mt. Katmai on the Alaskan peninsula on June 6, 1912. An ancient trail led through the valley, so that it was well-known to have been rich in plant and animal life, a favourite hunting ground of the natives. One of the first events in the Katmai eruption was the bursting forth of a new volcano, Nova Rupta, in the floor of one arm of the valley. Probably from this vent, and other smaller ones, issued the great flow of incandescent sand which filled the floor of the valley, 17 mi. in length and 4 mi. in width, utterly consuming everything in its path until it reached the lower end of the valley, where the trees were merely turned to charcoal. At the time of its discovery not ten thousand but millions of jets of steam were issuing from the floor of the valley from vents ranging in size from a tiny crack to pits or craters 150 ft. in diameter. In temperature they ranged up to 1,200° F., hot enough to melt zinc and to set ablaze a stick held in the steam. Immediately following the hot sand flow Mt. Katmai exploded. Its three-peaked snow-covered crown was blown to atoms, leaving a crater 3 mi. wide, containing a lake 3,700 ft. below the crater rim. Five cu m. of ash were thrown out, covering Kodiak Island, 100 mi. away, with a blanket a foot deep. Acid rains fell in Cordova, 360 mi. distant, while the fumes tarnished brass in Victoria, B.C., 1,500 mi. away. The haze was noted in Virginia and at the bureau of standards in Washington, D.C. The dust from Katmai thrown into the higher layers of atmosphere robbed the north temperate zone of 10% of the sun's heat in the summer of 1912. Because Katmai

VARIED SCENERY IN VALLEY OF TEN THOUSAND SMOKES

1. Ash covered snowdrift near intense heat of fumaroles (crevice in volcanic cone) making an ideal temporary refrigerator
2. Looking across a corner of the Valley of Ten Thousand Smokes from the rim of Novarupta
3. Lines of fumaroles across the valley, illustrating that the smokes spring largely from fissures traversing the floor
4. Apparatus for measuring temperature of a fumarole. This one was found to be 572°F.
5. Frying bacon over a fumarole. Clear steam rushes forth with sufficient pressure to lift frying pan into the air

is located in a region almost uninhabited, not a human being lost his life, though this eruption was one of the largest ever known.

The Valley of Ten Thousand Smokes and its neighbouring wonders were discovered by Robert F Griggs, director of the National Geographic Society's expeditions of 1915–16–17–18–19 This region proved to be so stupendous a volcanic laboratory as well as so rich in scenic value that in Sept. 1918 President Wilson set aside the whole district, comprising 2,697,590 ac. as the Katmai National monument. (L T G.)

VALLOMBROSA, a summer resort of Tuscany, Italy, in the province of Florence, reached by road (9 m.) from the station of S Ellero (which is 16 m SE of Florence) and 328 ft above sea-level, on the north-west slope of the Prato Magno chain. The former monastery was suppressed in 1866 A number of hotels have been built. Similar summer resorts are situated among the woods above the Casentino or upper valley of the Arno to the east, such as Camaldoli, Badia di Prataglia, etc. Camaldoli was the original headquarters of the Camaldulensian order, now partly occupied by an hotel Five hours' journey to the south of the last on foot and 7½ m. to the east of Bibbiena by road is the monastery of La Verna, 3,660 ft above sea-level, founded by St. Francis in 1215 on an isolated limestone peak Here he received the stigmata in 1224. The small Church of the Angels, erected by him, and the Chiesa Maggiore (begun in 1348) contain some fine terra-cotta reliefs by the della Robbia family

VALLOMBROSIANS, an order of monks under the Benedictine rule, founded by St John Gualbert, who, about 1030, withdrew to Vallombrosa, a shady dale on the side of a mountain in the Apennines, 10 m from Florence, and for some years led a completely solitary life Disciples, however, gathered around him, and he formed them into an order in which the cenobitical and the eremitical lives should be combined The Benedictine rule was the basis of the life; but every element of Benedictine life was eliminated that could interrupt the attention of the mind to God—even manual labour. The Vallombrosians spread in Italy and France, but they never had more than sixty houses

See the *Catholic Encyclopaedia*, art "Vallombrosians"; and Max Heimbucher, *Orden u Kongregationen* (1907), I. § 44.

VALMY, a small village on the main road between Verdun and Paris, just west of Ste Menehould, famous for the French victory of Sept. 20, 1792. Eastward of Valmy lies, roughly north and south, the long barrier of the forest of Argonne. Dumouriez, with the belated assistance of Kellermann, was attempting to hold this in September against the advance of the duke of Brunswick's German troops Heavy and continuous rains had made the chalky and clayey soil a greater obstacle even than the thick undergrowth and wild country, but the French revolutionary troops were unable to hold the forest In their previous conflicts with Austrian or Prussian troops they had met continuous, immediate and shameful defeat; and their morale was going from bad to worse The duke's forces broke through easily, not by the main road it is true, but to the north by a pass known as the Cross in the Woods In great haste, on the 19th, Dumouriez was able to withdraw under the cover of darkness the forces guarding the northern portions of the Argonne, which would otherwise have been cut off. and to complete his junction with Kellermann. By the morning of Sept 20 his army was on the flank of Brunswick's advance and was facing towards Paris, with its back to the Argonne It consisted chiefly of troops of the *ancien régime*, disorganized by the defection of their officers, and young and wholly untrained volunteers.

Dysentery, the long detour necessitated by his holding a northern pass, and the general badness of the Prussian communications forced Brunswick to attempt immediately to clear Dumouriez's force off his flank and make safe his sources of supplies. As soon as the heavy mist lifted on the morning of Sept 20, therefore, he commenced an attack on the French by heavy artillery preparation The French line was drawn up on a slight elevation, of which the most prominent feature was the famous mill of Valmy. Between them and the Prussians was a shallow depression of about a half to three-quarters of a mile in breadth; the Prussians were drawn up on the opposite undulation The French artillery, which was less heavy in metal than the German, was the sole important arm which had not been disorganized, and was able to reply effectively to the Prussian cannonade Early in the afternoon, however, the Prussian guns did tremendous damage by a lucky shot which struck the French ammunition reserves by the mill, blowing them up with a tremendous report and great damage. A German mercenary brigade in the French service broke, and the effect on the whole sorely-tried French line was such that Brunswick decided that the right moment had come for a general attack, and gave the signal.

The Prussians advanced *en échelon* under a severe fire, but steadily, some two-thirds of the intervening distance The shaky ranks of the French were rallied by Kellermann, and were more or less prepared to meet the attack, when the Prussians hesitated. and, still apparently without disorder, retreated to their original position Some mystery surrounds this, the central event of the battle it seems probable that the Prussian advance was impeded by unsuspected thick mud at the foot of the hill, as well as by the accurate French gunnery—the support of their own guns necessarily ceasing as they approached the French lines The cannonade continued till nightfall. Brunswick, having failed to defeat his enemy, realized that his position was strategically untenable and, after a few days, retreated (*See* FRENCH REVOLUTIONARY WARS)

VALOIS, COUNTS AND DUKES OF. The French countship of Valois (*pagus Vadensis*) takes its name from Vez (Latin *Vadum*), its early capital, a town in the department of the Oise From the 10th to the 12th century it was owned by the counts of Vermandois and of Vexin; but on the death of Eleanor, sister and heiress of Count Raoul V. (d 1167), it was united to the crown by King Philip Augustus Soon detached from the royal domain, Valois was the property of Blanche of Castile, widow of Louis VIII., from 1240 to 1252, and of Jean Tristan, a younger son of Louis IX., from 1268 to 1270. In 1285 Philip III gave the county to his son Charles (d. 1325), whose son and successor, Philip, count of Valois, became king of France as Philip VI in 1328 Sixteen years later Valois was granted to Philip's son, Philip, duke of Orleans, then passing with the duchy of Orleans in 1392 to Louis (d 1407), a son of Charles V, it was erected into a duchy in 1406, and remained the property of the dukes of Orleans until Duke Louis became king of France as Louis XII. in 1498, when it was united with the royal domain After this the duchy of Valois was held by Jeanne, countess of Taillebourg (d 1520), from 1516 to 1517, and by Marie, countess of Vendôme, from 1532 until her death in 1546; it was given to Catherine de' Medici, the widow of Henry II., in 1562, and in 1582 to her daughter, Margaret of Valois, the wife of Henry of Navarre In 1630 Louis XIII. granted Valois to his brother Gaston, duke of Orleans, and the duchy formed part of the lands and titles of the dukes of Orleans until the Revolution

The house of Valois, a branch of the great Capetian family, is thus descended from Charles, a son of Philip III, and has been divided into several lines, three of which have reigned in France These are· (1) the direct line (reigned 1328–1498) beginning with Philip VI; (2) the Orleans branch (reigned 1498–1515), descended from Louis, duke of Orleans, a son of Charles V.; (3) the Angoulême branch (reigned 1515–1589) descendants of John, another son of the same duke.

VALOIS, CHARLES DE (1671–1747), son of Adrien de Valois, was a distinguished numismatist, and formed a fine collection of medals, chiefly Roman. He became a pupil (1705), and associate (1714), and finally a *pensionnaire* (1722) of the Académie des Inscriptions et Belles Lettres. He published *Histoire des Amphictyons*, and collected a number of critical observations, anecdotes, and Latin poems of his father in *Velesiana* (1694) His *Éloge* by Fréret is in the *Mémoires de l'Académie des Inscriptions*, vol xxi p 234 (1747).

VALOIS, anciently a district of Picardy, part of the government of the Ile-de-France, bounded on the north by Soissonnais, on the east by Champagne, on the south by the Ile-de-France proper, and on the west by Beauvaisis. It included the towns of Crépy (capital), Morienval, Pierrefonds, Compiègne, Verberie, Pont-Sainte-Maxence, Senlis, Chantilly, Villers-Cotterets. Under

the Roman domination it belonged to the Suessiones but it is now a small area in the departments of the Oise and the Aisne.

At first governed by its own independent counts, Valois in 1214 was joined to the kingdom of France by Philip Augustus It has given its name to three lines of the second branch of the Capetian kings (*See* VALOIS, COUNTS AND DUKES OF)

For history *see* A. Poilleux, *Le Duché de Valois, pendant les XIVe et XVIe siècles* (1843).

VALONA (Albanian, *Vlonë*), a seaport of Albania Pop. (1930) about 9,100, of whom 65% were Muslims, 30% Orthodox and 5% Roman Catholics Valona occupies an eminence near the gulf of Valona and is almost surrounded by mountains. The port is the best on the Albanian coast, with good anchorage and shelter, being protected by the island of Saseno (the ancient *Saso*) It is a port of call, and the cable and telegraph line to Otranto, Italy, has an important station there. About 1½ mi. from the sea, Valona has a pleasant appearance with its minarets and its palace, surrounded by gardens and olive groves Valonia, a material largely used by tanners, is the pericarp of an acorn obtained in the neighbouring oak woods and derives its name from Valona. The surrounding district is mainly agricultural and pastoral, producing oats, maize, cotton, a little rice, olives, cattle, sheep, hides, skins and butter, all of which are exported, together with bitumen from the mine at Selenitsa At Smoktina there are steam sawmills, while in the town itself there are motor repair works and an oil refinery Valona played an important part in the wars between the Normans and the Byzantines during the 11th and 12th centuries In 1464 it was taken by the Turks, captured by the Venetians in 1690 but restored to Turkey in 1691. In 1851 it suffered severely from an earthquake During the Balkan Wars (1912–13) Valona was bombarded by the Greek fleet in 1912, and in the same year Ismail Bey proclaimed the independence of Albania In the following year the International Commission of Control sat at Valona and appointed Prince William of Wied king of Albania After his flight, a few months later, Valona was seized by the insurgents At the outbreak of World War I in 1914 the Italians seized Saseno, which had been ceded to Albania, and occupied the town itself, which they held until 1920. They occupied Valona again in 1939 The city was bombed heavily during the Greek-Italian war in 1940–41.

VALPARAÍSO, a province in the coast ranges of central Chile, smallest and most densely inhabited province in the country. Area 1,860 sq mi.; pop (1950) 528,326, most of which is in Valparaíso, capital of the province, and the suburban towns along the coast. The climate is mild and semiarid.

VALPARAÍSO, city and seaport of Chile, capital of province of the same name, on a broad open bay of the Pacific in lat 33° 0′ 2″ S, long. 71° 41′ 15″ W., 115 mi. by rail N W. of Santiago Pop. (1944) 209,945 The almost semicircular Bay of Valparaíso is slightly over 3 mi. across from Punta Angeles to Punta Gruesa, and the city stands on the south side, on the slopes of a spur of barren hills projecting into the Pacific and forming a rocky peninsula terminating in Punta Angeles. This point affords good shelter from southerly and westerly storms, but the bay is open to those from the north The extreme points of the bay are strongly fortified. The city occupies a narrow strip of beach around the head of the bay and extends up the steep slopes and valleys of the enclosing hills, which have an altitude of 1,000 to 1,400 ft The city's civic improvements are striking and beautiful. The Chilean naval academy buildings and fine residences are located on heights overlooking the bay. Improved roads connect the upper and lower city. There are numerous inclined passenger elevators. The suburban resort Viña del Mar is noted for its buildings, amusements and society.

Valparaíso is pre-eminently commercial and industrial, there are large foundries and factories producing chemicals, textiles, paints and clothing. The city's trade, normally the largest and most important on the Pacific coast of South America, makes it a terminal and port of call for several major steamship lines. In 1949, the foreign trade amounted to 687,200 tons imported and 89,300 tons exported compared with 732,000 imported and 98,000 exported in 1950. Trade with other Chilean ports included 170,996 tons in exports and 609,572 in imports in 1949 compared with 210 058 and 686,156 tons in 1950

An electrified line of the state railways connects the city with Santiago, and steam lines of the same system link Valparaíso with virtually all important cities and ports of Chile from Pisagua in the north to Puerto Montt in the south It is the western terminus of the Transandne railway, giving the city direct overland connection with Buenos Aires Air lines connect the city with other parts of Chile and with foreign countries Good highways extend northward from Valparaíso along the coast and to the national capital.

Harbour improvements, completed in 1930, represented an outlay of several million dollars Although the great depth of the water retarded progress, a breakwater more than 3,000 ft long was built to the western part of the inner bay, sheltering an area of approximately 123 ac. The depth in this part of the harbour is sufficiently great to accommodate the largest vessels afloat There are scores of piers, a mile of stone sea wall, warehouses and modern cargo-handling machinery

Valparaíso was founded in 1536 by Juan de Saavedra, who named it after his birthplace near Cuenca, Spain The port and town were of little note during the colonial period, for free commercial intercourse with the colony was forbidden. In 1819, near the end of the war with Spain, its population barely reached 5,000 In 1578 it was captured by Sir Francis Drake, and in 1596 by Sir John Hawkins.

In 1600 it was sacked by the Dutch under Oliver van Noort On March 31, 1866, it was bombarded by a Spanish fleet under Adm. Casto Méndez Nuñez, when a large part of the town was laid in ruins, and on Aug 28, 1891, after the victory of the congressional troops over José Manuel Balmaceda's forces in the vicinity, it was partially sacked by the Chileans themselves It suffered much from the earthquakes of 1731, 1822, 1839, 1873 and 1908 That of 1908 caused the destruction of a large part of the city. Its modernization may be said to date from the earthquakes of 1906–07 From ashes and debris streets were widened and paved, better business structures arose and modern sewerage was provided

VALPARAISO, a city of Indiana, U S, 40 mi. S.E. of Chicago; county seat of Porter county. It is served by the Grand Trunk, the Nickel Plate and the Pennsylvania railways and is on federal highway 30. Pop. (1950) 12,028 It is the seat of Valparaiso university, established 1871 as a revival of a Methodist college (1859–69), and from 1925 under Lutheran auspices; also of the Valparaiso Technical institute. Valparaiso was settled about 1836 and chartered as a city in 1865.

VALS (Vals-les-Bains), Ardèche, a town of southeastern France. Pop. (1946) 2,669. Vals is situated on the Volane among volcanic mountains. It is celebrated for its numerous cold mineral springs, impregnated in most cases with sodium bicarbonate They are used chiefly for drinking but also as baths and are efficacious in maladies of the digestion, liver and kidneys and for gravel and gout. Great quantities of bottles are exported

VALTELLINA (Ger. *Veltlin;* the name comes from the former capital, Teglio), properly the name of the upper valley of Adda, in north Italy. Historically, it also comprises the Italian Lire or San Giacomo valley, now the province of Sondrio

Pop (1936) 142,919. Today the whole valley belongs to the kingdom of Italy, except the side valley of Poschiavo (Puschlav), which belongs to the Swiss canton of the Grisons (Graubünden) The chief town is Sondrio (1936–7,639), other important places being Tirano (3,867), Chiavenna (3,823) and Morbegno (4,277) Near Bormio there are some frequented mineral springs (sulphur and lime), known in Pliny's time, and efficacious in diseases of the skin There are several other baths in the side valleys, such as Santa Caterina (chalybeate), Masino and Le Prese (sulphur).

The highest points in the ranges enclosing the valley are the Piz Zupo (13,117 ft) in the Bernina group and the Gran Zebrù (Königsspitze) (12,661 ft.) in the Ortler district; the Monte della Disgrazia (12,067 ft.) is the highest peak comprised entirely within the water-basin of the valley. Four well-marked Alpine passes are traversed by good roads—the Stelvio pass (9,048 ft., the highest carriage-road in Europe) from Bormio to Spondigna

in the Adige valley; the Bernina pass (7,645 ft.) from Tirano to Samaden in the Upper Engadine; and the Aprica pass (3,875 ft.) from Tirano to the Val Camonica and the Lake of Iseo, while from near the top of the Stelvio a fourth road leads over the Umbrail pass (8,242 ft, the highest in Switzerland) to the Swiss valley of Münster, which is reached at the village of Santa Maria. The main valley is traversed from end to end by a magnificent carriage-road constructed by the Austrian Government in 1820–25. A railway runs from Colico, on the Lake of Como, past Sondrio to Tirano, a distance of 42 m, while there is another from Colico to Chiavenna (16½ m.).

The population is wholly Italian-speaking and Roman Catholic, the valley being in the diocese of Como. The shrine of the Madonna of Tirano (founded 1520) attracts large numbers of pilgrims. The valley, particularly in its lower portion, is extremely fertile, and of late years vigorous measures have been taken to prevent the damage caused by the frequent inundations of the Adda. Chestnuts, vines, mulberry trees and fig trees abound; and there are many picturesquely situated churches, castles and villages The chief articles exported are wine and honey. Large quantities of honey are annually sent abroad The Valtellina has now become important for its hydroelectric plants.

History.—After the defeat of the Lombards (774) the Valtellina was given (775) by Charlemagne to the abbey of St Denis near Paris, which never seems to have exercised its rights. In 824 Lothair I., confirming an earlier donation (803) made by Charlemagne, gave the churches of Poschiavo and Bormio to the bishop of Como. Bormio was in 1205 won by the men of Como, who in 1006 had received one-half of Valtellina from the emperor, and by 1214 they were masters of the entire valley They retained Bormio till 1300, when it freed itself, but in 1336 it belonged to the bishop of Chur In 1335 the Visconti of Milan became lords of Como, and therefore of Valtellina. As early as 1360 the men of Rhaetia made incursions into Valtellina on the pretext that it had formed part of ancient Rhaetia. This idea was confirmed in 1404, when, in return for kind treatment received during his exile, Mastino Visconti (son of Barnabò) gave to the bishop of Chur his share of the Milanese, including Poschiavo, Bormio and Valtellina. Relying on this donation, the men of the three Leagues of Rhaetia (best known by the name of Graubünden) invaded the valley in 1486–87. Poschiavo becoming in 1486 permanently a member (not a subject land) of the *Gotteshausbund* In 1512 Chiavenna, Bormio and Valtellina were also seized and harshly ruled. Mastino Visconti's donation was solemnly confirmed in 1516 by the emperor Maximilian I In 1530 the bishop of Chur was forced to sell to the Three Leagues his title to these two districts. At the time of the Reformation Poschiavo became Protestant. The other two districts clung to the old faith and came under the influence of Carlo Borromeo. Valtellina was extremely important to the Habsburgs as affording the direct route between their possessions of the Milanese and Tirol. Hence a great struggle took place between Austria and Spain on one side and France and Venice on the other The religious conflicts in Graubünden led to reprisals in the "subject land" of Valtellina In 1620 (July 19–Aug. 4) the Spanish and Catholic faction (headed by the Planta family) massacred from 350 to 600 Protestants in the valley, according to different accounts (*Veltliner Mord* or *Sacro Macello*). For the next 20 years the valley was the scene of great strife, being held by the Spaniards (1621–23, 1629–31, 1637–39), by the French (1624–27, 1635–37) and by the pope (1623, 1627). At length George Jenatsch, a former pastor, who had been the active and unscrupulous leader of the Protestant party, became a Catholic (1635) in order to free the land from the French by aid of the Spaniards (1637), who finally (1639) gave it back to its old masters on condition that the Protestants were excluded from the valley In this way the local struggles of Valtellina came to be mixed up with the Thirty Years' War In 1797 Bormio and Valtellina were annexed to the Cisalpine republic, in 1805 to the Napoleonic kingdom of Italy and in 1815 (despite the remonstrances of the Rhetian leagues) to the kingdom of Lombardo-Venetia, held by the emperor of Austria. In 1859 they became, like the rest of Lombardy, part of the kingdom of united Italy. Poschiavo followed the fortunes of the "Gotteshausbund." It became (after 1798) part of the canton Rhetia of the Helvetic republic, and in 1803 of the canton of the Graubünden or Grisons, which was then first received a full member of the Swiss Confederation (*See* SWITZERLAND)

VALUATION AND VALUERS. A valuation or appraisement, under English law, need not be stamped where it is made (1) for, and for the information of, one party only, and is not obligatory as between parties; (2) in pursuance of the order of a court of admiralty or on appeal therefrom; (3) of property of a deceased person for the information of an executor, or other person required to deliver an affidavit of the estate of such deceased person; or (4) of any property for the purpose of ascertaining the legacy or succession or account duty payable in respect thereof. Any other valuation or appraisement must be stamped. Who makes an appraisement or valuation chargeable with stamp duty must, within 14 days after, write it out in words and figures showing the full amount upon duly stamped material. If he omits to do so, or in any other manner discloses the amount, he becomes liable to a fine Any person who receives from an appraiser, or who pays for the making of, any such appraisement or valuation not so written out and stamped, becomes liable to a fine

Where a contract has been made for the sale of property at a valuation, a valuation made in accordance with its terms will be conclusive as between the parties, in the absence of fraud, collusion or mistake Where there has been an agreement to sell goods on the terms that the price is to be fixed by the valuation of a third party and such third party cannot or does not make such valuation, the agreement is avoided; but if the goods or any part thereof have been delivered to and appropriated by the buyer he must pay a reasonable price therefor Where the third party is prevented from making the valuation by the fault of the seller or buyer, the party not in fault may maintain an action for damages against the party in fault. Where the fixing of a value by valuers is not of the essence of an agreement, but is wholly subsidiary to it, the courts will, if justice require it, ascertain the value in order to carry the agreement into effect Where an agreement had been entered into for the sale of a house at a fixed price and of the furniture at a valuation by a person named by both parties, and he undertook the valuation but was refused permission by the vendor to enter the premises for that purpose, the vendor was ordered to allow the entry so that the valuation might proceed

A person who exercises the calling of an appraiser or who, for or in expectation of any fee or reward, makes any valuation or appraisement chargeable with stamp duty, must (unless he is licensed as an auctioneer or house agent) have an appraiser's licence, upon which a duty is charged and which continues in force from the day of its date until the following 5th of July. By default in this respect a liability to a penalty is incurred. Moreover, an unlicensed appraiser cannot recover remuneration A valuer is liable to the person who has employed him for the consequences of negligence or want of due care and skill on his part If his services are thereby rendered worthless he will not be able to recover anything by way of remuneration (*See* AUCTIONS AND AUCTIONEERS; ESTATE AND HOUSE AGENTS.) (X.)

United States.—The American law conforms substantially to the English as stated above, save that there are no American stamp duties in reference to valuation There are, however, at least three additional fields in which valuation has assumed considerable importance in the United States One is a matter of private law, the other two, of constitutional law The first is the common legislative attempt to control stock-watering by providing that corporate stock shall be issued only in return for full par value in money or property, and giving creditors various civil remedies against directors or against those who receive stock without making adequate return. This raises immediately the question of valuation of property exchanged for stock. In substantial effect these statutes have proved inadequate to their purposes They leave no legitimate machinery for promoters to procure the profits which the courts themselves view as proper and necessary; hence there is persistent pressure to devise means of evasion. And

the courts show a distinct tendency to support valuations of the property arrived at "in good faith," which in practice regularly means some substantial addition to provable tangible assets, by way of the anticipated profits from their use And transfer of the stock to a bona fide purchaser is held to wipe out the creditors' claims against the stock. Furthermore, the introduction of no-par stock makes possible in many States to-day the complete disregard of the older regulations The second field is valuation for purposes of taxation Here the common practice is for the assessors to undervalue realty, so that tax valuation of realty is not admissible as evidence of value in a suit for any other purpose And such undervaluation becomes a constitutional right of the tax-payer, in so far as he is entitled not to have his holdings valued at their true worth, if other holdings of like character are undervalued by the assessors A more difficult problem is met in the apportionment of the intangible going value of an interstate enterprise, for taxation by the several States in which the enterprise is operated In the field of communication and transportation agencies, which have been chiefly concerned, the courts have in general worked out the permissible divisions by taking the total tax base of the enterprise (*e.g.*, gross income or value of outstanding securities, etc) and permitting any one State to reach its due proportion as calculated by the ratio of tangible assets (*e g* , miles of track) or traffic (ton-miles, car-miles, etc) inside the State to total tangible assets or total traffic The more recent cases show a definite trend toward nicer approximation to measurement of business actually done in the taxing State In the case of interstate business enterprises, the combined effects of the interstate commerce clause and of interlocking corporate structure produce a technical chaos incapable of brief exposition The third field is valuation for purposes of determining the rates chargeable by public utilities. On the one hand, such utilities as gas, railroad, water and telephone companies are subject to rate regulation by the government to prevent excessive charges On the other, they are private property, in the sense that rates may not be put so low as to be confiscatory "A fair return on fair value" is the legal formula applied It is clear, however, that value itself, in the market, depends wholly on the return from the assets, so that reference to market value to determine the "fair value" on which a fair return is to be allowed involves reasoning in a circle. This the courts have never expressly recognized, but in their actual decisions they have introduced other more stable factors by requiring any rate-regulating commission to "consider" certain phases of cost in determining the fair value. The emphasis has been strong on the reproduction cost of plant and equipment. Originally, this seems to have been influenced by a desire to avoid the padded original costs of early corporate exploitation; more recently, it is a reflection of rising costs of reproduction The valuers, in the first instance, are of course the railroad or public utility commissions of the States. It is clear that market value is by no means always the measure of value which is sought in legal valuation. (K. N. L.)

VALUE. In economics, use is made of three closely related conceptions of value: *exchange value, subjective value* and *imputed price.*

Exchange Value, or value in exchange. This denotes the relative importance which the community, as a whole, manifesting its preferences through the process of the market, attaches to a particular good (commodity or service) in comparison with other goods. It is often defined in the older treatises on political economy as "power in exchange." The exchange value of a particular "good" is measured or expressed by the quantity of other goods for which a unit of that good can be exchanged, or, preferably, as a ratio of exchange Any one good, of course, really has many different specific exchange values, corresponding to the various ratios at which it can be exchanged for different commodities and services The notion of the general exchange value of a good rests upon an inclusive view of all of its different specific exchange values The money price of a good is conceived of as one of its specific exchange values or, in other connections, as its general exchange value expressed in terms of money, which thus serves as a "common denominator of values." Because the direct barter of goods for goods is uncommon, the exchange values of different goods have to be inferred from their money prices. Indeed, the conception of exchange value is derived from the conception of price by making abstraction of the use of money as an instrument of purchase and sale This abstraction has been found useful in economics because, first, some aspects of important economic problems are seen more clearly when values are looked upon as though they were determined by the direct comparison of goods with goods without the intervention of money, and second, because it is often desirable to eliminate the effects which changes in the value of money have upon the money prices of different goods With the development of statistical technique, however, it has been found possible to take separate account of general changes of prices and of relative changes in the prices which are paid for particular goods For this and other reasons the conception of exchange value has lost some of the importance which it once had in economics Economic analysis now commonly deals, more directly and realistically, with money prices

Subjective Value.—This denotes the relative importance which an individual consumer attaches to a particular good, in comparison with other goods It relates always to specific quantities or specific increments or decrements of goods. Even an individsible good, an automobile for example, is a compound of various qualities, such as size, power, comfort and appearance, and buyers have a certain range of choice within which these qualities may be had in larger or smaller measure and combined in different proportions So far as a consumer chooses rationally rather than impulsively he apportions his outlays so that he would gain nothing by buying more of one thing and less of another Thus he brings his monthly or annual outlays for different purposes to or towards a common boundary or margin (his "margin of consumption") where the importance which he attaches to what he gets for the final or marginal pound or dollar which he spends, say for food, is equal to the importance of what he gets for the marginal pound or dollar spent for clothing or other object

Imputed Price.—This is an estimate of the amount of money for which a given article or a given quantum of goods could be sold or bought. When we say that the value of a work of art, a house, or a stock of goods is so many pounds or dollars, we are using the word value in the sense of imputed price. The "valuation" or appraisal of goods for purposes of taxation or of formal transfer is an imputation of price. A nation's wealth can be expressed in terms of its money value only by imputing prices to the various items of which it is composed. Value, in this sense, is not the price would could be got at a forced sale or the price which would have to be paid by buyers in order to induce holders to part with their goods *en bloc.* It is, instead, an estimate of the price which could be obtained in due course, with no sudden accelerating of either supply or demand. Statements to the effect that the price of a commodity is above or below its value generally mean only that because of a temporary excess of supply or demand or because buyers or sellers lack knowledge of facts which, if known, would affect their offers, the present price is out of line with the probable future price.

Theories of Value.—That the exchange value of a good is determined by the amount of labour required to produce it was at one time a fairly common belief. Adopted and restated by Adam Smith and his successors, this doctrine was later taken over by Karl Marx and other socialists and put into a form in which labour is held to be the sole source or cause of value. In its best form, as set forth by Ricardo, the labour theory of value was to the effect that, allowing for temporary fluctuations of supply and demand, the exchange values of different commodities tend to be *proportional* to the respective quantities of labour required to produce them. The rent of land was held to be without influence on the value of its produce, for the reason that the value had to be high enough to cover the labour costs incurred under the most unfavourable conditions of cultivation, where no rent is or can be paid. Capital was regarded as stored up labour, and interest or necessary profit on capital was disregarded on the arbitrary assumption that its amount would be roughly proportionate to the total amount of labour employed in producing a commodity

Apart from the circumstance that other costs than labour are not adequately brought into the reckoning, the labour theory of value encounters two difficulties First, different kinds of work call for different kinds and degrees of ability and training, and differ in respect of attractiveness Different kinds of labour can be fused into a "quantity" of labour only by grading them or weighting them in accordance with the different values which their respective products command in the market, and this procedure leads to circular reasoning Second, so far as there is, in fact, any systematic relation between quantities of labour and the values of products, it is a result of the circumstance that labour is apportioned to different tasks only in such proportion and degree as its different products are valuable Similar difficulties are encountered in any attempts to find a simple relation between values and "real costs"

Dissatisfied with explanations of values in terms of costs, some economists, taking note of the circumstance that values must necessarily be related to the choices and preferences of consumers, sought to find the determinant of value in marginal utility (*i e*, the utility or importance to the buyer of the least important or "marginal" part of his current consumption of any commodity). Subjective values are proportionate to marginal utilities and exchange values must be proportionate to subjective values. If they were not, the consumer would alter his budget by buying more of one thing and less of another. Each consumer thus adjusts his purchases so as to bring his own valuations into line with the values which obtain in the market, but the values which obtain in the market are the resultants of the aggregate demand of consumers for different products This aggregate demand determines what and how much shall be produced and what the values of different uses of labour and of other productive agents shall be. Such, in brief outline, is the marginal utility theory of value It illuminates some aspects of the problem, but it is quite as one-sided and incomplete as a cost-of-production theory of value is. That consumers' preferences determine what shall be produced and what costs of production shall be incurred is no more true than that the relative costs of producing different things determine how far consumers can follow their preferences.

Displacement Costs.—The costs which are most directly and systematically related to values are displacement costs. Labour displaces other uses of time, saving displaces present consumption, any one use of labour or capital or natural resources displaces other uses, and in general, the production of one good displaces the production of other goods The production of some goods can be increased with a progressively smaller sacrifice of other possible products. Other goods can be had in larger quantities only by sacrificing progressively larger amounts of alternative products As the amounts of a given good which have to be sacrificed in order that other goods may be acquired change, consumers will alter their budgets, but how far they will go will depend upon the relative importance to them of the uses of the increments of goods which they acquire and of the increments which they sacrifice Out of the play of forces such as these, and especially out of the relation between the preferences of consumers on the one hand and the technical conditions which determine the displacement costs of production on the other hand, there emerges a tendency—never fully effective because of continuous changes in the structure of demand and in the conditions of supply—towards the establishing of a system of exchange values which would bring production and consumption fully into equilibrium.

VALUE, THEORY OF. Until recently there has been no general theory of value Value has long been a fundamental notion of political economy and various theories of its nature have been developed, but it is only in the last decades that it has been universally recognized as one of the great philosophical topics. Its discovery has been held by some to be "the greatest philosophical achievement of the 19th century," and its development as a special field of psychological and philosophical study has gone so far that a special name has been created for it, namely *Axiology*.

The development of such a theory requires the consideration of the following problems: (1) What is the nature of values? (definition), (2) What are the fundamental values and how are they to be classified? (3) How may we determine the relative values of things and what is the ultimate standard of value? (4) Are values merely subjective, satisfying merely subjective desires, or are they objective, in some sense other than objects of desire, and giving some law or norm to desire? (5) What is the relation of values to things or of value to existence and reality?

The History of the Value Notion.—A brief sketch of the history of the idea of value in philosophy will help to make clear the meaning of these problems The Greeks did not have the term value as now understood, but in the light of subsequent developments we may see that they had the notion, and were aware of these problems Plato conceived the good or value as the culmination of the world of ideas and the constructive principle of the world which organizes all its forms or laws. Aristotle, in proposing to view all things teleologically, and to make the relation of a thing to its end or value essential to its very being, affirmed, not only the objective reality of value qualities, but also their supremacy over all the other attributes of things. Neither Plato nor Aristotle developed this line of reflection fully, nor did succeeding philosophers investigate the subtle and perplexing problems involved in it. Plato himself called this the most difficult question of all science. Nevertheless, the general principle enunciated by Greek philosophy continued to be the rule throughout the middle ages, and the objectivity of value the key to all their thinking.

The modern developments of the subject proceed directly from Kant who here, as elsewhere, represents a crisis in philosophic thought. The classical conception of the objectivity of the good or value had been abandoned by modern empirical thought If the so-called "secondary" qualities, such as colour, taste, sound, etc are made dependent upon the percipient subject, all the more must the "tertiary" qualities, such as beauty, goodness, etc. be made dependent upon human desire and feeling This extrusion of all values from the objective world seemed to Kant to be the necessary consequence of the assumptions of "science." But he could not accept it as the whole story of values By a well-known line of reasoning which cannot be repeated here, he restored their objectivity in a new form. Though not "existent" in the same sense as physical things, their reality must be postulated and acknowledged, if life and action are to be possible They have, in his terms, "validity" and "practical reality." With this an entirely new line of thought was set in motion, raising new problems of fact and value, value and validity, value and existence A large part of modern axiology or general theory of value has developed under the inspiration of Neo-Kantianism. But it is to R. H Lotze (1817–81) more than any other man perhaps except Nietzsche, that the popularity of the term value is due, and certainly he more than any other is responsible for the prevalence of the idea of value as an ultimate notion in philosophy. Albrecht Ritschl (1822–89), Lotze's theological colleague at Göttingen, made the value notion central in the discussions of religion and theology and furnished modernist tendencies in theology with a large part of their inspiration and much of their terminology He agrees with Kant that the objects of religion are objects of faith as distinct from knowledge in the scientific sense, but he develops much further the notion that they are matters of value judgment as distinct from theoretical judgment, although equally capable of certainty and validity. It is mainly to Ritschl that is due the current distinction between judgments of value and judgments of fact, and the subordination of judgments of fact to judgments of value. From Ritschl's position it was easy to pass to that of W Windelband (1848–1915) who, together with H Rickert and Hugo Munsterberg (1863–1916) developed the Neo-Kantian axiology to which reference has been made

The chief stimulus to the development of the general theory of value as a distinct field of psychological and philosophical study, came, however, from the work of A. Meinong (1853–1920) and C von Ehrenfels (1859–1932). A fresh analysis of value in the economic sense had been undertaken by the Austrian economists, Boehm Bauwerk and Von Wieser, which resulted, among other things, in raising many problems of psychological and even philosophical importance. Under their influence, Meinong and Von

Ehrenfels investigated values other than economic, and first undertook a systematic study of the entire field of value. The more philosophical developments of the subject are largely due to Meinong Starting with the psychological concept of the economists he gradually came to the view of values as objective and independent of their being experienced At this point the problems of the two modern movements described tended to coalesce No history of value theory would, however, be complete that did not note the influence of Nietzsche, with his "transvaluation of all values," and the Pragmatic movement in philosophy, for which knowledge is subordinated to practice and truth becomes a form of value

The Nature of Value.—The fundamental problem of a general theory of value is the question of the nature of all determinations of value, in other words of so defining it as to include all the forms of value. The immediate and natural answer to this question is to say that value is a determination or quality of an object which involves *any sort of appreciation or interest*. Such appreciation, however, involves feeling and ultimately desires or tendencies underlying the feeling Therefore value *is* the feeling Value and feeling of value are the same thing This is the psychological notion of value and the theory of value developed on this basis the *psychological theory of value* For many this seems to tell the whole story. The economic theory of value made its first scientific steps by abandoning the notion of value, whether in use or exchange, as an objective quality inherent in the thing, and conceiving it as the function of the relation of the object to satisfaction of desire Following this lead, the general theory of value was in the first place a psychological theory of value. Even in economic theory, however, it is realized that this is only part of the story. Back of desire and feeling lie certain biological tendencies or instincts presupposed by the desire and its satisfaction. So that value becomes, in the words of Orestano, "a biological phenomenon appearing in psychological form." A theory of value that shall be not merely a theory of *price* must relate the *instrumental* values of economics to life. Unless we consider these tendencies merely in their aspect of determinants of price, we must have a quite different notion of value to include them If this is true of the limited field of economic goods or values, it is all the more true of the *intrinsic* values which a more general theory of value recognizes. Psychological theories of value thus tend to become biological theories in the broader sense of the term. Value is defined in terms of survival and enhancement of life, and the biological tendencies are graded according to some standard of value-for-life. It is at this point, however, that the specifically philosophical theories of value arise We wish to explain and ultimately validate these values by carrying them back to life. But in this it is already assumed that life and its continuance have value. If values get their significance from their teleological relation to life and its enhancement, then surely life must get its significance from "absolute" values which it embodies, otherwise life and its relative values lose all genuine meaning. From a more ultimate point of view a knowledge of value is presupposed in any concept of a valuable life. As the result of reflections of this type, two main positions have emerged in the general philosophical theory of value. Either value is conceived of as a "logically primitive" concept, and therefore as ultimately indefinable, as are certain other ultimate concepts in philosophy, or else it is conceived of as function of the coherent organization of life or experience as a whole.

It may be said without hesitation that value theory is to-day predominantly philosophical rather than psychological This does not mean, however, that the psychological study of the processes of valuation is not an important part of the general theory. The psychological question is what goes on in consciousness when we value, and while an answer to this question will neither tell us what value ultimately is, nor afford us a standard of value which will enable us to form a system or scale of values, it nevertheless throws light on many questions. The most important contributions here are, perhaps, the studies of the mutations or transvaluations of values. The popular interest aroused by Nietzsche in his *Genealogy of Morals* has found a scientific echo in the study of the phenomena, causes and laws of the mutations of values.

A notable feature of modern value theory is the interpretation of history as a value science, or part of a philosophy of values.

Classes and Standards of Value.—It is generally admitted that distinct species of value exist, although there is no complete agreement as to what they are or how they are to be classified. It is clear, however, that there are sciences which deal with values and special sciences have been developed to deal with special classes of value. Thus economic value has long been recognized as a fundamental notion of political economy, which ever since Adam Smith divided it into value in use and value in exchange has been defined thus. the former as the utility of objects for human purposes and the latter the power to induce or compel people to pay other valuables for the use of them. That ethics also deals with values is generally agreed, although there is dispute as to just what these values are and how they are related. It is now generally recognized that ethical value is not identical with pleasure or happiness, although pleasure is one of the values Aesthetic values are also generally, although not universally, admitted, many pragmatists holding that, since valuation is always judgmental, and the aesthetic "has no logical function, it must be denied the name of value" From the philosophical standpoint, the most important group of values distinguished is perhaps the logical or theoretical values. Several schools of thought hold that logic is the science of cognitive values and that truth is a positive and error a negative value. Indeed this view is quite generally implied although it is not always explicitly avowed. "Religious values" are quite commonly talked about, although whether they constitute a special group or represent rather a fusion of, or a reaction to, the other values is a matter of dispute It may be argued that they do not constitute a distinct class, because there is no specific biological tendency or instinct to which they correspond, or that they represent merely the reaction on the fate of the other values in the universe. But the tendency to recognize the value of the "holy" as a distinct type, as developed by the Neo-Kantians, is very strong, and has recently found expression in a much read book, *The Holy*, by Rudolf Otto. Some writers speak of distinct classes of social and political values, but the general tendency, perhaps, is to view these as sub-forms of the ethical.

Despite such differences of opinion, incidental to any developing theory, there is substantial agreement as to the existence of these four outstanding classes of values. There is, unfortunately, not the same consensus of opinion regarding their relations, *i.e.*, the ordering of these values in a system or in a scale of relative value and importance There are in general three accepted ways of classifying them. There is the psychological which, assuming values to be the functions of interests or desire, divides them according to modes of this interest and tends to become ultimately biological and genetic, the outstanding classes being connected with some fundamental "instinct" or tendency. A more historical mode of classification accepts as units those values, or groups of values, which have acquired an institutional form, such as economic, moral, cognitive, political, aesthetic, religious. A third, which has been called the axiological, accepts in the main the trinity or tetrad of the good, the beautiful and the true, to which it adds the higher unity of God Such classifications or systems of value all have their uses, but it is generally felt that the first two are not sufficient. A large body of opinion, accepting the "axiological" classification, holds that while the economic values are clearly instrumental and relative to the others, the other groups are intrinsic and absolute, and as such ultimately co-ordinate. Others hold that they may be put in relations of subordination in a comprehensive scale of values. There are, however, some things that may be said with a certain degree of assurance. The ethical, aesthetic and logical values are self-sufficient and co-ordinate in the sense that they are irreducible the one to the other. All attempts at such reduction, whether, for instance, of the aesthetic to the ethical, of the ethical to the logical or the logical to the ethical, have proved unsatisfactory On the other hand, it seems clear that they are all intimately related No intrinsic value can stand alone. This is equally true whether we consider the question from the standpoint of the realization of values in the individual life or from the more objective point of view of their logical relations.

It is impossible to define any one type of value alone or apart from the others The ancient view that values are subsumable under the heads of goodness, beauty and truth, "a threefold cord, not lightly broken," is in general strengthened rather than weakened by modern value theory.

The idea that these ultimate values are co-ordinate in the sense described does not, however, as might at first appear, exclude the notion of an ultimate standard of value in the light of which some hierarchical principle or scale of value might be developed, and the classes of values be subordinated to each other. On the general question of the commensurability of value as such, there is a large measure of agreement. For the opinion, held by a few, that they are incommensurable, there is indeed something to be said. It may be objected that an economic satisfaction and an aesthetic experience are of such different inner qualitative content that it is absurd to compare them with each other The fact remains that we do actually compare them constantly. We compare values not only within the same class, as when we choose one economic good rather than another; we also choose between types and classes. The standpoint of the incommensurability of values can be admitted only in the sense that the different values cannot be expressed in quantitative units and measured in this sense. But there are few that hold this idea at the present day. For the merely psychological or biological theories, the standard of value is found in such conceptions as intensity of feeling, the strength of the desire, or ultimately in the importance for life of the biological tendencies presupposed. For the more philosophical theories, on the other hand, that recognize the limitations of these notions of value, a different conception of the ultimate standard is also necessary In general such a standard is found in the notion of *inclusiveness*, in some functional conception such as the totality of life or experience, that value being highest which contributes most to the coherent functioning and organization of experience as a whole Such a standard may be formulated in terms that seem to avoid metaphysical implications, but in general it may be said that the highness or lowness of an experience of value is held to be determined by its metaphysical content From this point of view a very common table or scale of values is that which puts the economic values as the lowest and the religious (in the broadest sense) as the highest, the ethical, the logical and the aesthetic being arranged in various ways in between The standard here employed is, in the last analysis, some form of the principle of inclusiveness, the different values being arranged either in accord with the degree of integration of our interests or tendencies, or in accord with the range of the metaphysical content to which they correspond

Logical or Theoretical Values—Validity.—The inclusion of logical or theoretical values in the general theory of value is undoubtedly the main reason for the outstanding place which axiology has in present day thought. Such an inclusion obviously involves a radical revision of our entire notion of values and of the relation of value to fact and truth. It is pointed out by the value philosophers that for an ultimate analysis, logic is also a science of values. The Pragmatists insist that theoretical values "presuppose purposes, selections, choices," and that "judgments are acts which do not differ in kind from those which are openly practical." The Neo-Kantian axiologists point out that the desire for truth and rationality, the demand for logical consistency or validity, is itself a craving for what *ought to be* and that here too we are moved by an ideal and directed by a norm, as surely as in the realms of ethical and aesthetic values. In either case validity becomes a form of value and logical rules instruments of the will to truth. The development of this notion involves difficult problems which cannot be gone into here. Whether the "value" of truth is relative or absolute, whether truth is the ultimate value upon which all the others in some way depend, or merely subordinate and instrumental to the other values; or, finally, in some way co-ordinate with them—all these are debated questions which, as we have seen, in turn affect the problems both of classification and order of values. In any case, the notion of validity as a form of value has brought about in many quarters a radical revision of our notion of the relation of value to fact and truth Against purely intellectualistic or "scientific" views it is contended, not only that every fact is ultimately an evaluation, but also that the logical impulse ought not to have the primacy over the other demands of our nature, and that no philosophical system can be adequate which fails to do justice to all our values. Philosophic system tends to become, from this point of view, a system of values, or at least to presuppose such a system.

Value and Reality.—Whatever differences of opinion there may be among the various theories of value, there is substantial agreement that values are not subjective in the sense that they are merely matters of opinion and exist only for the persons who appreciate or feel them Even for the psychological-biological theory, while they are dependent upon interest (desire and feeling), they are independent of judgment and opinion The "objectivity" thus universally accorded values is indeed given different meanings, but in any case it is now generally agreed that values cannot be denied existence or reality in any world that can exist for man. They must, it would seem, exist in several senses

Values "exist" (1) in the sense that they are operative and effective in and on human minds and in human action, and find embodiment in the objective institutions of society. They are "real" in the sense that they are valid, that is they claim to be true ideals as opposed to false ideals or fictions. They must, however, be real in a still more ultimate sense (metaphysical), in that they are part of the nature of things, and not something merely added to existences. For values to be real in either of the first two senses they must be real in the third. For both must be so related to real existence that they constitute the key to the nature of the real Otherwise they become false ideals and futile fictions. The question of just how values may be said to exist (to be part of the nature of things) is a difficult and debated question that cannot be gone into here. It is possible, however, to state a general proposition to which almost all theories of value would subscribe. Values are not mere subjective incidents, more or less gratuitously superadded to fact, but are inherent in the structure of reality Reality in its fullness contains and exhibits values, and they can be extruded from it only by a process of abstraction that is relative to restricted purposes (of special sciences) and which is never quite successful This reinstatement of the objective reality of [illegible] philosophy [illegible] philosophy [illegible] the present [illegible] *Value* (1926). Refs. to the more extensive liter. will be found in an art. by W. M. Urban, written in prep. for the Sixth Inter. Congress of Philosophy, entitled *Value Theory and Aesthetics*, and pub. in the *Monist* for Oct., 1926. Important works in general philosophy in which the value notion is central are Hugo Munsterberg *Eternal Values* (1909); B. Bosanquet *The Principle of Individuality and Value* (1912), and the *Value and Destiny of the Individual* (1913) (rep. the idealistic point of view); S. Alexander *Space, Time and Deity* (rep. the realistic and naturalistic point of view); and W. R. Sorley *Moral Values and the Idea of God* (1919). The Ger. and Fr. lit. is even more extensive Only a few of hist. import and of recent pub. can be noted. Among these are Ch. V. Ehrenfels *System der Wertheorie* (1897); A. Memong *Zur Grundlegung der Allgemenen Wertheorie* (1923); G. Simmel *Philosophie des Geldes* (1900); H Rickert, *System der Philosophie*, 1921; W. Stern *Wertphilosophie* (1924); C. Bergner *La Notion de Valeur* (1908); C Bougle *L'Evolution des Valeurs* (1922). (W. M. U.)

VALVES (MECHANICAL) are devices for controlling the flow of air, gases, or liquids. They vary from the small air-valve in the automobile tyre to huge valves for controling the flow of large volumes of water in such engineering developments as the locks of the Panama Canal.

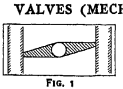

FIG. 1

One of the simplest types is the valve shown in fig 1. This is made in all sizes up to about 10 ft. in diameter in water-pipes and is known as the butterfly-valve. This valve is similar to the

damper used in stove-pipes. Another simple type is the flap-valve which is used as a check-valve in hand-pump pistons, to allow water to pass through the plunger on the down stroke and to prevent its return on the lift stroke. A similar valve (fig. 2) is also used between steam boilers and the pump or other method of supplying the boiler with water. When the water pressure is withdrawn, the steam pressure in the boiler forces the valve to its seat and retains the water in the boiler. In another form of check valve the stem guides the valve to its seat.

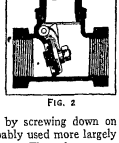

FIG. 2

It is but a step from this to the globe-valve in fig. 3 where the valve is closed by screwing down on the valve stem. This type of valve is probably used more largely than any other in controlling water and steam. The valve seat in fig. 3 is usually separate from the valve stem. In most cases the seat can be easily removed when worn and replaced. In some designs of simple globe-valves, the seat can also be replaced when worn.

FIG. 3

In a later design of globe-valve, which has replaced the valve in fig. 3 to a considerable extent, the valve acts as a gate in the line of flow, and does not compel the liquid or gas to take such a circuitous route as in the globe-valve. Gate-valves are made with both straight and angular seats. When the angular seat is used, the gate acts as a taper wedge between the seats. When the seats are parallel, the wedging action is secured by a tapered piece on the valve stem being forced between the two discs. The valve openings in both types are usually round, as when placed in a pipe line and forming part of it. In exceptional cases, however, the valves are rectangular, as in some of the gates of the intakes of the Panama Canal locks.

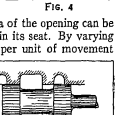

FIG. 4

A valve used largely in high pressure work and for securing fine adjustments of the opening, as in spraying or atomizing, is known as the needle-valve (fig. 4). The area of the opening can be varied very slightly as the needle is moved in its seat. By varying the angle of the needle point, the opening per unit of movement can be varied between wide limits. This type of valve is used in spraying fuel into Diesel engine cylinders.

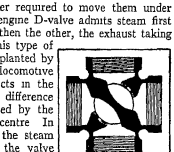

FIG. 5

Valves for admitting steam or gas to engines are either sliding, rotary or poppet. The slide-valve is among the oldest types used for this purpose, but has largely disappeared, owing to the power required to move them under high pressure. The old steam engine D-valve admits steam first to one end of the cylinder and then the other, the exhaust taking place in the central cavity. This type of valve has now been largely supplanted by the piston-valve, particularly in locomotive use. A piston-valve (fig. 5) acts in the same way as the D-valve, the difference being that the valve is balanced by the steam at each end or in the centre. In some cases, the admission of the steam takes place at the centre of the valve and the exhaust from each end.

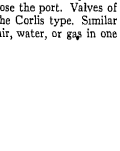

FIG. 6

Rocking- or rotary-valves are also used for similar purposes. Such valves admit steam in one position and block its flow when turned so as to close the port. Valves of this kind were used on steam engines of the Corliss type. Similar valves are also used to direct the flow of air, water, or gas in one or more directions at will. They are frequently known as three-way or four-way valves. A four-way valve is shown in fig. 6. When moved from one position to another, the flow is directed into any of the pipes shown. The simplest form of rotary-valve is the plug cock in fig. 7. (For gasolene engines of the poppet and sleeve types *see* MOTOR CAR, *Valves.*)

Safety-valves, for relieving the pressure of boilers, pressure tanks, or pipe lines, may be said to be check-valves held to their seats by weights or springs set so as to open when the desired blowing-off pressure has been reached. Safety-valves are made in a variety of forms, the older type having a lever with a weight placed at the proper point to give the desired pressure. Loaded valves have springs over the valve seat instead of the lever. (F. H. C.)

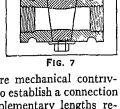

FIG. 7

VALVES or **PISTONS,** in music, are mechanical contrivances applied to wind instruments in order to establish a connection between the main tubing and certain supplementary lengths required for the purpose of lowering the pitch. Various devices have been tried from the days of ancient Greece and Rome to produce this effect, the earliest being the additional tubes inserted into the lateral holes of the aulos and tibia (*qq v.*) in order to prolong the bore and deepen the pitch of each individual hole, these tubes were stopped by the fingers in the same manner as the holes. This device enabled the performer to change the mode or key in which he was playing, just as did the crooks—or coils of tubing inserted between the mouthpiece and the main tube in the trumpet and horn, and between the slide and the bell joint in the trombone—many centuries later.

But the resourcefulness of the ancients did not stop there. The tibiae found at Pompeii had sliding bands of silver, one covering each lateral hole in the pipe; in the band were holes (sometimes one large and one small, probably for semitone and tone) corresponding with those on the pipe. By turning the band the holes could be closed, as by keys, when not required. By fixing the δδοί in the holes of the bands, the bore was lengthened instantly at will, and just as easily shortened again by withdrawing them; this method was more effective than the use of the crooks, and foreshadowed the valves of eighteen centuries later. The crooks, or coils of tubing inserted between the mouthpiece and the main tube in the trumpet and horn, and between the slide and the bell joint in the trombone, formed an important step in this direction.

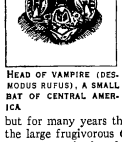
Although the same principle underlies all these methods, *i.e.*, the lengthening of the main column of air by the addition of other lengths of tubing, the valve itself constitutes a radical difference, for the adjustment of crooks demands time and the use of both hands. The action of the valve being as instantaneous as that of the key, the instrument to which it was applied was at once placed on a different basis, becoming a chromatic instrument capable of the most delicate modulations from key to key.

The slide had already accomplished this desirable result, but as its application was limited to instruments of which the greater part of the bore was cylindrical, *i.e.*, the trumpet and trombone, its influence on concerted musical composition could not be far-reaching. In fact it is doubtful whether the chromatic possibilities of the slide were fully realized until the end of the 18th century, when, key mechanism having made some advance, it was being applied successfully to the transverse flute, and to the clarinet and oboe families.

In 1760 Kölbel, a Bohemian horn-player engaged in the St Petersburg Imperial Orchestra, turned his attention to this method of extending the compass of brass instruments. His experiments, followed up by Anton Weidinger of Vienna at the beginning of the 19th century, produced a trumpet with five keys and a complete chromatic compass. Halliday followed with the keyed bugle in 1810. Halary applied the principle of the keyed bugle to the bass horn in 1817, and produced the ophicleide—an ideal chromatic bass as far as technical possibilities are concerned. The horn had become a chromatic instrument through Hampel's discovery of

bouché sounds, but the defects in intonation and timbre still remained Such were the conditions when the successful application of the valve to brass wind instruments by Heinrich Stolzel of Silesia brought about an entire revolution in the design and construction of these instruments Further efforts to perfect the key system as applied to the brass wind were abandoned in favour of valves, and the short space of two decades witnessed the rise of the Flugel-horns, the tubas, the saxhorns and the cornet-à-pistons, the trombone, French horn and trumpet having led the van

Although the valves of brass wind instruments vary in form and detail according to the makers, the general principles governing their action are the same for all types. The piston, placed on some branch of the main tube, must be so constructed that on being depressed it closes the natural windways through the main bore and opens others into the additional piston length The piston, seated on a spring, instantly regains its normal position when the finger is removed. The length of tubing attached to each valve is calculated on the basis of the length of the main column, to give for the first piston a tone, for the second a semitone, for the third a tone and a half, and for the fourth two tones.



There was, however, a difficulty at first In the early valved instruments it was found that the intonation of the notes yielded by the combined pistons was seriously inaccurate, an increase in the length of the additional tubing being required to give the right results, and it took many years before the instrument-makers succeeded in satisfactorily overcoming this defect and producing the perfected instruments of the present day

Although the accredited inventor and patentee of valves applied to musical instruments was Heinrich Stölzel, of Pless in Silesia, the actual inventor was really one Blumel, also a Silesian, who sold his rights to Stölzel in 1815.

VAMBERY, ARMIN (1832–1913), Hungarian Orientalist and traveller, was born of humble parentage at Duna-Szerdahely, a village on the island of Shütt, in the Danube, on March 19, 1832 He was educated at the village school until the age of 12, and owing to congenital lameness had to walk with crutches. At an early age he showed remarkable aptitude for acquiring languages, but straitened circumstances compelled him to earn his own living After being for a short time apprentice to a ladies' tailor, he became tutor to an innkeeper's son. He next entered the untergymnasium of St Georgen, and proceeded thence to Pressburg Meanwhile he supported himself by teaching on a very small scale, but his progress was such that at 16 he had a good knowledge of Hungarian, Latin, French and German, and was rapidly acquiring English and the Scandinavian languages, and also Russian, Serbian and other Slavonic tongues At the age of 20 he set up as teacher of European languages in Constantinople, and shortly afterwards became a tutor in the house of Pasha Hussein Daim. Under the influence of his friend and instructor, the Mollah Ahmed Effendi, he became, nominally at least, a full Osmanli, and entering the Turkish service, was afterwards secretary to Fuad Pasha After spending six years in Constantinople, where he published a *Turkish-German Dictionary* (1858) and various linguistic works, and where he acquired some 20 Oriental languages and dialects, he visited Tehran; and then, disguised as a dervish, joined a band of pilgrims from Mecca, and spent several months with them in rough and squalid travel through the deserts of Asia. He succeeded in maintaining his disguise, and on arriving at Khiva went safely through two audiences of the khan. Passing Bokhara, they reached Samarkand, where the emir, whose suspicions were aroused, kept him in audience for a full half-hour; but he stood the test so well that the emir was not only pleased with "Resid Effendi" (Vámbéry's assumed name), but gave him handsome presents. He then reluctantly turned back by way of Herat, where he took leave of the dervishes, and returned with a caravan to Tehran, and subsequently, in March 1864, through Trebizond and Erzerúm to Constantinople By the advice of Prokesch-Osten and Eötvös, he paid a visit in the following June to London; there his daring adventures and linguistic triumphs made him the lion of the day In the same year he published his *Travels and Adventures in Central Asia* In connection with this work it must be remembered that Vámbéry could write down but a few furtive notes while with the dervishes, and dared not take a single sketch, but the weird scenes, with their misery and suffering, were so strongly impressed on his memory that his book is convincing by its simplicity, directness and evidence of heroic endurance Vámbéry also called the attention of politicians to the movements of Russia in Central Asia. From London he went to Paris; then returning to Hungary, he was appointed professor of Oriental languages in the University of Budapest. there he settled down, contributing largely to periodicals, and publishing a number of books He died at Budapest on Sept 15, 1913

His travels have been translated into many languages, and his autobiography, *Arminius Vámbéry, his Life and Adventures* (1883; 9th ed., 1914), was written in English. Amongst the best known of his works, besides those alluded to, are *Wanderungs and Adventures in Persia* (1867); *Sketches of Central Asia* (1868), *History of Bokhara* (1873); *Manners in Oriental Countries* (1876); *Primitive Civilization of the Turko-Tatar People* (1879), *Origin of the Magyars* (1882), *The Turkish People* (1885), *Hungary* (1887), with Heilprin, and *Western Culture in Eastern Lands* (1906).

VAMPIRE, a term originally applied to bloodsucking ghosts, now transferred to blood-eating bats inhabiting South America. In its original meaning a vampire is supposed to be the soul of a dead man which quits the dead body at night to suck the blood of living persons. Hence, when the grave is opened, the corpse is found to be fresh. To put a stop to his ravages the commonest method is to drive a stake through the body. The belief in vampires is still prevalent among Slavonic peoples. (*See* also DEMONOLOGY.)

HEAD OF VAMPIRE (DES. MODUS RUFUS), A SMALL BAT OF CENTRAL AMERICA

The blood-eating bats comprise three genera (*Desmodus*, *Diphylla* and *Diaemus*) from the forest of tropical America. Their attacks upon men and warm-blooded animals were noticed by early writers, but for many years the bats themselves were not identified and the large frugivorous *Glossophaga soricana* and *Vampyrus spectrum* were mistaken for the true sanguivorous species. *D. rufus* is the more abundant species; it is a small bat, about 3 in. in length with reddish-brown fur, and peculiar teeth (*see* fig.) adapted to its mode of feeding. They are said to be able to pierce the skin and lap up blood without awakening their victim. The oesophagus is very narrow, as is the pyloric division of the stomach, while the cardiac part is produced into a large diverticulum. *D. ecaudata* is less abundant, confined to Brazil, and differs in the details of the teeth.

VAN. (1) The chief town of a vilayet of the same name in Asiatic Turkey; altitude, 5,400 ft. Pop. (1940) 11,785. It is situated about a mile from the eastern shore of Lake Van, and built along the south side of the citadel rock, an isolated rocky ridge 1,300 yd. long, rising 360 ft. out of a plain which extends up to the sharply defined rocky mass of the Varak range, 8 m distant. On the gently sloping ground east of the citadel are the Gardens, covering an area of 5 m. by 3, and containing several suburbs and detached houses, along central avenues fringed with trees, and having channels of running water by the sides for irrigation.

The town itself is a poor place with flat-roofed mud houses, narrow winding streets, and surrounded by a ruinous mud wall, but it still contains the business quarter, the government offices and the principal bazaars. Water comes from *karez* or underground channels and streams from Varak, fed from the Sikhe Lake, an ancient reservoir which preserves the snow waters on the summit of the mountain For the southern quarter there is the Shemiram Canal, also of very ancient construction, which derives its supply from a large spring 19 m distant, near Meshningird The climate is generally healthy, extremely cold in winter, with 2 to 3 ft. of snow from December to March, while the summer heat is not excessive. The Persian trade of Van has declined, European goods, with which the bazaars are fairly well supplied, come from Trebizond through Erzerum. There is a fair local trade in wheat and agricultural produce, also sheep and cattle, wool, hides and furs for export.

The cuneiform inscriptions of Van are very numerous, the town

having been the capital of the Vannic kingdom of the Assyrian period, for which *see* URARTU

In the sixth century B C. Van passed into the hands of the Persians, and shortly before it fell to Alexander the Great it was rebuilt, according to Armenian historians, by a native prince called Van. In 149 B C Valarsaces or Vagharshag, the first Armenian king of the Arsacidae, rebuilt the town, and a colony of Jews was settled in it by Tigranes (94–56 B C.) In the middle of the 4th century A D it was taken by Sapor (Shapur) II, and became the capital of an autonomous province of the Sassanian Empire, until it fell into the hands of the Arabs (*c* 640), under whom it regained its autonomy About 908 the governor of Van or Vaspuragan was crowned king by the caliph Moktadir, and in 1021 his descendant Senekherim was persuaded by Basil II to exchange his kingdom for the viceroyalty of the Sebasteian theme. After having formed part of the possessions of the Seljuks, Mongols, Tatars and Persians, Van passed in 1514, after the defeat of Shah Ismail by Selim I at the battle of Kalderan, to the Osmanlis, who only occupied the town in 1543 In 1636 it was taken by the Persians, but soon recovered In 1845 the town was held for a time by the Kurd chief Khan Mahmud

(2) The vilayet of Van lies along the Persian frontier between the vilayets of Bayazid and Hekkiari. Pop. (1940) 112,975. The mineral wealth of the vilayet is believed to be great.

(3) LAKE VAN, called Arsissa Palus and also Thospitis from its Armenian names, is roughly rectangular 55 mi long and 40 broad, with a long northeastern arm which increases the greatest length to 80 mi. It stands about 5,260 ft. above sea-level. It is without an outlet, and its greatest depth is along the southern shore. It has constant steady fluctuations, rising and falling some 8 ft in a periodic movement of five years In the middle of the 19th century a sudden rise submerged several places on the banks, including Arjish Kale, and the waters did not subside. The northeastern arm is much shallower than the rest. The water is bitter and undrinkable, being largely impregnated with carbonate and sulphate of soda with some borax The salts are evaporated in pans, and called *perek*, being sold for washing purposes. There is, however, good water along the coast from springs and streams The lake has been navigated from the earliest times, and sailing boats, carrying about 20 tons burden, now ply on it, chiefly with wheat and firewood. Severe storms make navigation dangerous in winter. The southern shore is fringed by a steep range of mountains, with several thriving villages along the coast. The hills have been almost denuded of trees. At the southeastern corner is the island of Akhtamar with its ancient church, erected (*c.* 928) by Gagig, first king of the Ardzrunian dynasty. The Catholicos of Akhtamar was one of the highest offices in the Armenian Church, and dated from 1113 Large numbers of *darekh*, a kind of herring, exist in the lake, and are caught in nets from boats or when they enter the shallow lagoons in the spring and summer. Fresh or salted they form an important article of diet of the poor.

VANADINITE, a mineral consisting of lead chloro-vanadate, $(PbCl)\,Pb_4\,(VO_4)_3$, crystallizing in the hexagonal system and isomorphous with pyromorphite and mimetite (*q.v.*). The crystals are usually six-sided prisms terminated by the basal planes, but are sometimes modified by numerous pyramidal planes which exhibit parallel hemihedrism. Rounded crystals and groups also occur. The colour is usually light brown or yellow, but crystals from Arizona are brilliant scarlet. Owing to isomorphous replacement of the vanadium by phosphorus and arsenic, the specific gravity varies from 6.6 to 7 2; a variety containing much arsenic is called *endlichite*. The mineral is one of secondary formation in veins of lead ore. In New Mexico and Arizona it has been mined as a source of vanadium for the manufacture of vanadium-steel. Several occurrences are known in South Africa.

VANADIUM, a metallic chemical element belonging to a family which also includes columbium (*q v*) and tantalum (*q.v.*). Although one of the rarer elements, vanadium (symbol V, atomic number 23, atomic weight 51), is fairly widely distributed, and since its application in the production of special steels (*see* STEELS, ALLOY), several of its minerals have been extensively exploited.

Occurrence.—Patronite, native vanadium sulphide, which is an important source of the metal, occurs in Peru associated with iron pyrites in coal deposits. Carnotite, potassium uranyl vanadate, $K_2O_2UO_3V_2O_5.3H_2O$, is found in Colorado and Utah and is extensively worked for vanadium, radium and uranium Vanadinite $[Pb_3Pb_3(VO_4)_3]Cl_2$, isomorphous with pyromorphite and mimetite, occurs as deep red crystals in Arizona, New Mexico, South East Africa and Northern Rhodesia Other vanadium minerals are descloizite, a lead zinc vanadate found in New Mexico and Arizona, and roscoelite, a micaceous mineral in which aluminium is partially replaced by vanadium; the latter occurs in Colorado and is an important source of the metal Mottramite, a basic vanadate of lead and copper, is found in Cheshire In addition to these minerals in which it is a major constituent, vanadium occurs in numerous rocks and deposits Many iron ores such as the minette of Lorraine and the German and Swedish iron ores contain as much as 0 3 to 0 7% of vanadium pentoxide

A new metal was first observed in vanadinite by M. Del Rio (1801). Subsequently N G. Sefstrom (1830) isolated its compounds from the slag of Taberg iron and having noticed the beautiful colours which they displayed in solution, he called the new metal vanadium, in allusion to Vanadis, a name sometimes given to Freya, the Scandinavian goddess of beauty. F. Wöhler (1830) showed that vanadium was identical with Del Rio's erythronium and a more extended study of the metal and its compounds was made by J J Berzelius (1831). In 1868 H E Roscoe proved that the supposed vanadium obtained by the earlier investigators was chiefly the nitride or oxide of the element and by a brilliant application of the principle of isomorphism, he showed that vanadium was a member, together with phosphorus and arsenic, of Group V of the periodic classification.

Extraction of Vanadium Oxide from its Minerals.—Patronite is roasted and fused with sodium carbonate, the sodium vanadate thus formed is extracted with water, and the addition of ammonium chloride then precipitates ammonium vanadate On ignition this salt leaves vanadium pentoxide. The vanadium when dissolved as vanadate may also be precipitated as calcium or ferrous vanadate The native vanadates, carnotite, mottramite, etc, are extracted with concentrated hydrochloric acid; the acid extract and washings are evaporated with ammonium chloride, when ammonium metavanadate separates. (For further details of separation consult special treatises indicated in the bibliography.)

Metallic Vanadium.—The metal was first obtained by Roscoe on passing hydrogen over the heated dichloride. It is also prepared by reducing the pentoxide with "mischmetall," a mixture of the rare-earth metals. It has been prepared by the aluminium reduction method from vanadium trioxide and by the electrolysis of sodium vanadate in hydrochloric acid

Vanadium is a silvery white metal with specific gravity 5·5 to 5·89; its melting point is 1,710° C. The fusibility is diminished by the presence of vanadium carbide or oxide. Vanadium is stable in air and is unacted on by bromine water, aqueous alkalis, hydrochloric acid or cold sulphuric acid It is dissolved by hydrofluoric acid or hot sulphur acid to green solutions. Molten potash or potassium nitrate attacks the metal forming potassium vanadate. Its alloy with aluminium containing up to 10% of vanadium is malleable. Cuprovanadium is an alloy employed in copper castings and bronzes

Ferrovanadium.—The greater part—about 90%—of the vanadium extracted is used in form of ferrovanadium alloys containing 25 to 30% of vanadium. Such alloys are produced by the "thermite" process on iron vanadate, by the reduction of this compound with carbon in the electric furnace, or by electrolysis of vanadium pentoxide dissolved either in fused ferrosilicon or in a molten mixture of iron fluoride and calcium carbide. When vanadium is added to steel it effects the removal of oxygen and nitrogen carrying these into the slag, and the portion which remains in the metal increases the tensile strength, toughness and elastic limit of the steel These improvements are effected by comparatively small amounts ranging from 0·05 to 0·5%.

Compounds of Vanadium.—Vanadium salts are used as catalysts in a variety of chemical operations. A trace of vanadic acid accelerates the oxidation of cane sugar by nitric acid (*See* MESOXALIC ACID and OXALIC ACID.) A very small amount of vanadyl sulphate promotes the development of aniline black. Vanadium pentoxide has been utilised as a catalyst in bringing about the combination of sulphur dioxide and oxygen to sulphur trioxide, and in the aerial oxidation of naphthalene to phthalic anhydride, benzene to maleic anhydride and benzoquinone, toluene to benzaldehyde, and anthracene to anthraquinone. Vanadium resinate and linoleate have been employed as driers for linseed oil and other drying oils, the action being more rapid than that induced by lead or manganese salts. Ammonium vanadate has been used in leather dyeing and other vanadium salts have been employed in photography and chemotherapy, where vanadium arsenate and salicylate have produced beneficial effects, the latter as a substitute for salvarsan

Vanadium exhibits five stages of valency, each stage giving rise to characteristic colours. An acid solution of vanadium pentoxide, V_2O_5, is yellow to orange; mild reducing agents convert to the V_2O_4 stage which is characterised by a deep blue colour. Further reduction of $VOCl_2$ leads to a green solution, now containing hydrated trichloride, VCl_3, corresponding with the V_2O_3 stage Drastic reduction gives rise to a lavender solution of VCl_2 corresponding with the VO stage A lower oxide, V_2O, is described but is unimportant.

Vanadium pentoxide, V_2O_5, made by igniting ammonium metavanadate, NH_4VO_3, crystallises in yellowish-red prisms sparingly soluble in water but dissolving in aqueous alkalis to vanadates and in acids to vanadic salts such as $(VO)_2(SO_4)_3$ Metavanadic acid, HVO_3, is obtained as a brown powder by boiling copper vanadate with nitric acid, and when produced from this vanadate by digestion with ammonium chloride it separates in gold spangles known as "vanadium bronze" and employed as a pigment Vanadic acid and its oxide V_2O_5 enter into many complex combinations:—polyvanadates, phosphovanadates, arsenovanadates, molybdovanadates and tungstovanadates Vanadyl chloride, $VOCl_3$, a yellow liquid boiling at 127° C, is prepared by passing chlorine over heated vanadic oxide, but when carbon or sulphur is present vanadium tetrachloride, VCl_4, is also obtained as a reddish-brown liquid boiling at 154° C. Vanadium tetroxide, V_2O_4, is a blue infusible substance obtained by mild reduction of the pentoxide; it dissolves in acids to yield blue vanadyl salts such as $VOSO_4$ and $VOCl_2$ and in aqueous caustic alkalis to brown solutions of the alkali vanadates (also termed hypovanadates); the potassium salt is $K_2V_4O_9{,}7H_2O$.

Vanadium trioxide, V_2O_3, a black infusible powder produced by reducing the heated pentoxide in hydrogen, dissolves slowly in hydrochloric acid to yield vanadium trichloride, the green solution of which is more readily prepared by reducing vanadic oxide with magnesium and hydrochloric acid. Anhydrous vanadium trichloride, VCl_3, prepared by heating vanadium pentoxide in chlorine and sulphur chloride, forms bluish-red crystals resembling anhydrous chromic chloride.

Vanadium trisulphate, $V_2(SO_4)_3$, a crystalline yellow powder, combines with sulphates of ammonium, potassium, rubidium and caesium to form vanadium alums. (*See* ALUM.) Vanadous oxide, VO, a grey powder having metallic lustre and metallic conductivity, is obtained by reducing the higher oxides with potassium. It was erroneously regarded as a metal by Berzelius and shown to be an oxide by Roscoe. The corresponding vanadous chloride, VCl_2, produced by reducing the tetrachloride with hydrogen, forms light green crystals dissolving readily to a lavender solution.

Vanadium acetylacetone, $V\{CH(CO\,CH_3)_2\}_3$, obtained by the interaction of vanadium trichloride, acetylacetone and aqueous sodium carbonate, crystallises from chloroform in dark brown tabular prisms melting at 185–190° C, and on exposure to moist air undergoes oxidation to bluish-green vanadyl acetylacetone, $VO\{CH(CO\,CH_3)_2\}_2$, also prepared by dissolving vanadyl hydroxide, $VO(OH)_2$, in alcoholic acetylacetone (G. T. Morgan and H W. Moss, 1913).

Vanadium forms three sulphides, V_2S_3, V_2S_5 and VS, the most stable of which is the trisulphide. The nitride, VN, produced by direct combination of its constituents, forms a metallic powder formerly confused with the metal itself The carbide, VC, an electric furnace product, forms hard silvery white crystals melting at 2750° C.

VANADIUM STEEL. The desirability of adding vanadium to certain steels has been known since 1896, but it was too rare to be used until 1905 when a rich deposit was discovered in Peru. Since then many minor localities have been worked, so that while ferrovanadium is still expensive, owing to the difficulty with which it is reduced and refined, there is ample raw material for present use Vanadium has a great chemical affinity for oxygen and nitrogen dissolved in steel; to avoid waste it is only added to deadmelted steel after all other quieting additions have been made Even so, some of it slags off, the residual analysis in engineering alloy steels being usually 0·15 to 0·25% Vanadium forms very stable carbides in steel, reluctant to go into solution when heated above the critical temperature for quenching, and reluctant to accumulate into discrete particles on tempering. The first-mentioned property contributes to the maintenance of fine grain (toughness) over a considerable range of quenching temperatures; the second contributes to strength and toughness at high operating temperatures These actions supplement the characteristic effects of other alloys present

Chromium-vanadium steels are now widely used for axle forgings, chain gears and springs, where strength, hardness, impact and fatigue resistance are a requisite The Society of Automotive Engineers' standards include several alloys with carbon from 0·15 to 0·55%, manganese from 0·50 to 0·80% (even higher with higher carbon), chromium from 0·80 to 1·10% and vanadium from 0·15 to 0·25%. These low alloys will give about the same properties after heat treatment as the nickel-chromium steels (*q v.*). Case-hardened articles made of the lower carbon contents have intense surface hardness and wear resistance; to intensify the skin hardness such steels are frequently quenched from a cyanide bath, and the vanadium is said to prevent the usual embrittlement caused by nitrogen

Carbon-vanadium steels are mostly used in the annealed state for locomotive castings or forgings and are preferred over other alloys which must be heat treated, because subsequent heating at shops unequipped for precise work will not seriously reduce their strength. Locomotive frames of cast steel containing 0·20% vanadium have an elastic limit 25% above that of a similarly annealed plain carbon casting, without any loss in ductility. Locomotive side rods, driving axles and large shafting for electrical machinery or reciprocating engines are frequently forged of carbon-vanadium steels, made in the acid open-hearth furnace Before machining they are usually air cooled from just above the critical range to refine the grain, and then annealed at just below the critical range to relieve all internal strains. (*See* IRON AND STEEL.) (E. E. T.)

VAN BEERS, JAN (1821–1888), Belgian poet, usually called "the elder" to distinguish him from his son, Jan van Beers, the painter, was born at Antwerp on Feb 22, 1821 Van Beers started life as a teacher of Dutch language and literature, first at Malines, then at Lierre, and in 1860 was appointed a professor of both at the Athenaeum (high school) in Antwerp, where he had also been a sub-librarian in the communal library. Van Beers's historical poems, the principal of which is, perhaps, *Jakob Van Maerlant* (Amsterdam, 1860), helped the Flemish revival in Belgium He is best known, however, as the writer of ballads and songs Among the best are *De Blinde* ("Blind"), *De Zieke Jongeling* ("Young and Doomed"), *Bij 't Kerkportaal* ("At the Church Porch"). Van Beers's poetry, full of glow and pathos, simple yet forcible, is somewhat akin to that of Longfellow. In 1884 his poems were collected in a volume, Van Beers died at Antwerp on Nov 14, 1888

VANBRUGH, SIR JOHN (1664–1726), British dramatist and architect, was born in the parish of St Nicolas Acons in the City of London, and christened on Jan 24, 1664 His father was a sugar baker, and his grandfather, Gillis van Brugg, came to England from Ghent in James I's reign The Vanbrughs left London during the Plague and went to Chester. After a few years at the King's School, Chester, John at nineteen was sent to France to study the arts, after two years' absence he returned to take up a commission in the regiment soon to be known as the 13th Foot. In the early autumn of 1690 Vanbrugh was arrested at Calais on a charge of espionage, on the information of a lady He was imprisoned at Vincennes, but on Feb 1, 1692, by a *lettre de cachet*, he was removed to the Bastille. His enforced leisure was responsible for the first draft of the *Provok'd Wife*. For a time after his return he resumed his commission

The production of Cibber's *Love's Last Shift* at the Theatre Royal in January 1696 kindled afresh his attachment to the comic muse. He thought it would be interesting to develop the situation upon which Cibber had rung down the curtain, and the result was *The Relapse*, "got, conceived and born in six weeks' space." It was given on Boxing Day 1696, with Cibber as Foppington, one of the three parts borrowed from the preceding comedy The Sir Novelty Fashion of Cibber was developed in this play into Lord Foppington, who has been pronounced "the best fop ever brought upon the stage." Foppington, Tunbelly Clumsy and Miss Hoyden are as fine a trio of comic characters as any play can show *Aesop* at Drury Lane followed This ran for a week only, but the success of *The Relapse* was so triumphant that Montague, afterwards Lord Halifax, asked at once for the *Provok'd Wife* for the theatre in Lincoln's Inn Fields, and it was produced at that theatre in May 1697. Sir John Brute, the husband, is Vanbrugh's masterpiece, and as usual the servants' characters are well drawn. The play was a complete triumph, and Brute was one of Garrick's great parts Vanbrugh was fiercely attacked by Jeremy Collier for immorality in 1698, and wrote nothing more for the stage until 1700, when an adaptation of the *Pilgrim* of Beaumont and Fletcher was produced at Drury Lane. In this play, in the part of Alinda, Anne Oldfield scored her first success Two years later appeared *The False Friend*, a version of Le Sage's *Traître puni*. Other adaptations from the French were *A Country House*, from Dancourt's *Maison de campagne*; *Confederacy* (1705), from the same author's *Bourgeoises à la mode*; *Squire Trelooby* (1704), a version of Molière's *Monsieur de Pourceaugnac*; and *The Mistake* (1705), from Molière's *Dépit amoureux* As a dramatist Vanbrugh is less polished than Congreve, and less remorseless than Wycherley He was not primarily a man of letters, and, as Cibber said, his dialogue is "common conversation committed to paper." No one would trouble to defend his dramatic morality, but his worst efforts are less repulsive than Wycherley, because there is less ruthless realism and more fun in his attitude. His plays are farce, very often, rather than strict comedy, and warmed with humour

Collier's attack and the resulting movement must have been responsible in part for "Van" turning his attention to architecture. The demand for splendid country seats in the new Palladian style was steadily increasing, and his reputation as a modern wit was an introduction in itself. In 1702 he was entered as comptroller of the Royal Works (now the Board of Works, where several of his designs may still be seen) In 1703 he wrote to ask his friend Jacob Tonson to procure him a "Palladio," and in the same year he was a commissioner at Greenwich In the meantime, Vanbrugh had been appointed architect to the earl of Carlisle, and the result, completed in 1714, was the Corinthian mansion of Castle Howard. The work is an extension of the Palladian plan introduced by Inigo Jones, with the addition of immense corridors in segmental colonnades leading from the main entrance to the wing blocks From a scenic artist's point of view, it is a magnificent (and certainly his best) piece of work. The earl procured for Vanbrugh a high place in the College of Arms. In March 1704 he was actually promoted Clarenceux, though he not only knew nothing of heraldry but had openly ridiculed that grave science in *Aesop*. His next work was to prepare designs for Kneller Hall near Hounslow. But the success of Castle Howard now caused him to entertain the rash project of building a theatre in the Haymarket, from his own design, for the acting of his own plays. Congreve joined in the venture. The magnitude of Vanbrugh's architectural ideas grew as the work went on, and with the ideas the structure grew till a theatre meant for the delicate *bijouterie* work of polite comedy seemed growing to the proportions of the Roman Colosseum. When at length the time came to test the acoustics of the pile, it was found to be sadly defective What changes were made to rectify the errors of structure does not appear The theatre was opened to the public with an Italian opera, which was followed by three of Molière's comedies, and these by the *Confederacy*, Vanbrugh's masterpiece

Vanbrugh at last withdrew from the disastrous speculation; Congreve had already withdrawn But a man to whom Fortune had been so kind as she had been to Vanbrugh could hardly be depressed by any of her passing frowns Queen Anne at once sent him abroad on an important state errand, and afterwards he was commissioned to build Blenheim Upon the merits and demerits of this famous "hollowed quarry" there has been much conflict of opinion Blenheim Palace is probably the largest domestic building in England, and consists of three blocks, the centre containing the private living rooms, one wing the stables, and the other the kitchens and storehouses It is planned on a colossal scale Vanbrugh considered a building and the parts of a building as simply so much material for effect, without regard to their reasonable use and the necessary limitations of design. Personal comfort was sacrificed to perspective. Windows were to adorn the elevation, not to light the interior; and, as Voltaire said, if the rooms had only been as wide as the walls were thick, the château would have been convenient enough. After Blenheim and Castle Howard, his next largest palace was probably Fleurs, near Kelso Blenheim, however, was a source of great sorrow to the kindly dramatist Though parliament had voted for the building of it, no provision had been made for the supplies The queen while she lived paid them, and then Vanbrugh was left to the mercies of the duke of Marlborough, and after this to the insolence of the "wicked woman," who did her best to embitter his life. Besides Castle Howard and Blenheim, he built many other country mansions, such as Grimsthorpe and Duncombe Hall in Yorkshire, Eastbury in Dorsetshire.

In January 1719 Vanbrugh married Henrietta Maria, daughter of Colonel Yarborough of Heslington, and four years afterwards, at the accession of George I, he was knighted. He afterwards wrote again for the stage, and the unfinished fragment of the *Journey to London* (completed by Cibber as *The Provok'd Husband* in 1728) shows that his powers remained to the last as fine as ever. His married life was mostly spent at Blackheath, very probably in "Bastile House" on Maze Hill, repaired in 1904 and now known as Vanbrugh Castle. His wife died there at a great age in 1776, but "Van" himself died on March 26, 1726 in his modest town house in Whitehall. The site is occupied to-day by the War Office The famous epitaph, "Lie heavy on him, earth," is attributed to Abel Evans.

Vanbrugh's works were edited in 2 vols., 1893, by W. C Ward (portraits); *Select Plays* were issued in the Mermaid Series (ed. A E. H. Swaen) in 1896 *See* G. H Lovegrove's *Life, Works and Influence of Sir John Vanbrugh* (1902), Max Daniel's *Vanbrughs Leben und Werke* (1898), and *Swift's Works* (Bohn), xii. 80 sq. *The Complete Works of Sir John Vanbrugh* (Plays and Letters) edited by B Dobree and G Webb (Nonesuch Press, 1928), with introduction by B Dobree

VAN BUREN, MARTIN (1782–1862), 8th president of the United States, was born at Kinderhook, N.Y., on Dec 5, 1782, of Dutch descent. His father was a farmer and tavern-keeper. His education was limited to that which could be obtained in the common schools and at Kinderhook academy. In 1796 he began the study of law, completing his preparation in 1802 at New York, where he studied under William Peter Van Ness (1778–1826), an eminent lawyer and later Aaron Burr's second in the duel with Alexander Hamilton. In 1803 he was admitted to the bar and continued in active and successful practice for 25 years. His prac-

tice made him financially independent, and payed the way for his entrance into politics New York politics after 1800, the year of the election of Jefferson and the downfall of the Federalists, were peculiarly bitter and personal The Republicans were divided into three factions, followers respectively of George Clinton (and later of his nephew, De Witt Clinton), Robert R. Livingston and Aaron Burr, and such Federalist control as there was from time to time after 1799, depended upon coalition with one or other of these groups. Van Buren, who early allied himself with the Clintonians, served as surrogate of Columbia county from 1808 to 1813 In 1812 he entered the State senate, in which his career covered two terms (1812–20). In 1815 he became attorney general, an office which he held, still as a member of the senate, until 1819, when he was displaced to make room for a Federalist He had already, in 1808, removed from Kinderhook to Hudson, and in 1816 he took up his residence in Albany, where he continued to reside until he entered Jackson's cabinet in 1829. As a member of the State senate he supported the War of 1812 He was chosen to draft the resolution of thanks voted by the legislature to Gen Andrew Jackson after the battle of New Orleans He broke with De Witt Clinton in 1813, but nevertheless favoured, in 1817, Clinton's plan for the Erie canal. His attitude towards slavery at the moment was shown by his vote, in Jan. 1820, for a resolution opposing the admission of Missouri as a slave State. It is at this point that Van Buren's connection began with so-called "machine politics," a connection which has made his name odious to some historians of the period. He was a leading member of the "Albany regency," a group of politicians who for more than a generation controlled the politics of New York and powerfully influenced those of the nation, and who did more than any other agency to make the "spoils system" a recognized procedure in national, State and local affairs. Van Buren did not originate the system, for it was already well developed when he entered public life; but the nickname of "Little Magician" which presently attached to him testifies to the skill with which he exploited it.

In 1821 he was elected to the U.S. Senate in which his course was not altogether consistent, though in this respect he is not to be judged more harshly than some of his associates. He at first favoured internal improvements, and in 1824 proposed a constitutional amendment to authorize such undertakings, but the next year took ground against them. He voted for the tariff of 1824, then gradually abandoned the protectionist position. He early recognized the availability of Andrew Jackson, however, as a presidential candidate, and after the election sought to bring the Crawford and Jackson followers together, at the same time strengthening his control as a party leader in the Senate. Always notably courteous in his treatment of opponents, he showed no bitterness either towards J Q Adams or Henry Clay, and voted for Clay's confirmation as secretary of State notwithstanding the "corrupt bargain" charge; at the same time he opposed internal improvements and declined to support the proposal for a Panama Congress. In the debate on the "tariff of abominations" in 1828 he took no part, but voted for the measure in obedience to instructions from the New York legislature—an action which was cited against him as late as the presidential campaign of 1844 Van Buren was not an orator, but his more important speeches show careful preparation and his opinions carried weight; and the oft-repeated charge that he refrained from declaring himself on crucial questions is hardly borne out by an examination of his senatorial career. In 1827 he was re-elected to the Senate and became one of the recognized managers of the Jackson campaign.

In 1828 Van Buren was elected governor of New York for the term beginning Jan 1, 1829, and resigned his seat in the Senate. But on March 5 he was appointed by President Jackson secretary of State and he resigned the governorship. As secretary of State he took care to keep on good terms with the "kitchen cabinet," the group of politicians who acted as Jackson's advisers, and won the lasting regard of Jackson by his courtesies to Mrs. John H. Eaton, wife of the secretary of War, with whom the wives of the cabinet officers had refused to associate. He did not oppose Jackson in the matter of removals from office, but was not himself an active "spoilsman," and protested strongly against the appointment of Samuel Swartwout (1783–1856), who was later a defaulter to a large amount as collector of the port of New York. He skilfully avoided entanglement in the Jackson-Calhoun imbroglio. In the controversy with the Bank of the United States he sided with Jackson After the breach between Jackson and Calhoun, Van Buren was clearly the most prominent candidate for the vice presidency Jackson, in Dec 1829, had already made known his own wish that Van Buren should receive the nomination. In April 1831 Van Buren resigned and in August he was appointed minister to England, arriving in London in September. He was cordially received, but in February learned that his nomination had been rejected by the Senate on Jan. 25. The rejection was in fact the work of Calhoun, the vice president; when the vote was taken enough of the majority refrained from voting to produce a tie and give Calhoun his longed-for "vengeance." No greater impetus than this could have been given to Van Buren's candidacy for the vice presidency In May the Democratic convention, the first held by that party, nominated him for vice president on the Jackson ticket. No platform was adopted, the widespread popularity of Jackson being relied upon to win success at the polls. Van Buren's declarations during the campaign were vague regarding the tariff and unfavourable to the United States bank and to nullification, but he had already somewhat placated the South by denying the right of Congress to abolish slavery in the District of Columbia without the consent of the slave States. In the election he received 189 electoral votes, while Jackson received 219 for president. Jackson now determined to make Van Buren president in 1836. In May 1835 Van Buren was unanimously nominated by the Democratic convention at Baltimore. He expressed himself plainly during the canvass on the questions of slavery and the bank. In the election Van Buren received 170 electoral votes against 73 for William Henry Harrison, his principal opponent; but the popular vote showed a plurality of less than 25,000 in a total vote of about 1,500,000. The election was in fact a victory for Jackson rather than for Van Buren.

The details of Van Buren's administration belong to the history of the United States (*see* UNITED STATES). He took over all but one of Jackson's cabinet, and met with statesmanlike firmness the commercial crisis of 1837 No exhibition of ability or courage, however, nor yet the most skilful manipulation of the political machinery of the party could prevent continued hostility to him and to the methods for which he was widely believed to stand. Nevertheless, he was unanimously renominated by the Democrats in 1840 Charged with being "a Northern man with Southern principles," his nomination obviously failed to arouse enthusiasm or even inspire confidence. Yet the election of Harrison, the Whig candidate, was less of a revolution than many affected to think. On the expiration of his term Van Buren retired to his estate at Kinderhook, but he did not withdraw from politics or cease to be a figure of national importance He confidently expected to be nominated for president in 1844 but in the Democratic convention, though he had a majority of the votes, he did not have the two-thirds which the rule of the convention required, and after eight ballots his name was withdrawn. In 1848 he was again nominated, first by the "Barnburners" faction of the Democrats, then by the Free Soilers, with whom the "Barnburners" coalesced, but no electoral vote was won by the party. In the election of 1860 he voted for the fusion ticket in New York which was opposed to Abraham Lincoln, but he could not approve of President Buchanan's course in dealing with secession, and later supported Lincoln He died in Kinderhook on July 24, 1862. His memoirs, to 1834, were published in 1920 under the title, *The Autobiography of Martin Van Buren*

Van Buren was married in 1807 to Hannah Hoes (1783–1819).

The best biography of Van Buren is by Edward M. Shepard, in the "American Statesmen Series" (rev ed, Boston, 1889). The life by George Bancroft (1889) is highly eulogistic Von Holst's *United States*, MacDonald's *Jacksonian Democracy*, Garrison's *Westward Extension* and T C. Smith's *Parties and Slavery* (the last three in the "American Nation Series") give much attention to Van Buren's public career. The Van Buren mss. are in the Library of Congress *See* also James Schouler, "The Calhoun, Jackson and Van Buren Papers," Mass. Hist Soc. Proc, and ser., vol xvii, p 459–465 (Boston, 1903); "Correspondence Between George Bancroft and Martin Van Buren,"

Rep., 1918, vol. 2, p. 7–808 (1920), Denis Tilden Lynch, *Martin Van Buren* (1929)

VAN BUREN, a city of Arkansas, U.S.A., 5 mi. N.E. of Fort Smith, on the Arkansas river and federal highways 64 and 71; county seat of Crawford county, served by the Frisco and the Missouri Pacific railways. Pop. (1950) 6,413. Van Buren is in the centre of the coal and gas fields of western Arkansas. Its industries include canning, preserving and freezing food. Founded in 1836, it is famous as the birthplace of Cyrus Adler, world-famous Jewish educator, and Bob Burns, radio and motion-picture star. It was incorporated in 1842.

VANCOUVER, GEORGE (*c.* 1757–1798), English navigator, was born in 1757. He entered the navy at the age of 13, and accompanied James Cook in his second (1772–74) and third (1776–80) voyages of discovery. After serving for several years in the West Indies, both under Rodney (his commander in the action of April 12, 1782) and under Alan Gardner (1786–89), Vancouver, on Gardner's recommendation, was appointed to command an expedition to the north-west coast of America, to take over from the Spaniards the territory they had seized (and subsequently relinquished) in that region, to explore the coast from 30° N. round to Cook's River (or Inlet), to search for an eastward passage to the Great Lakes, and to ascertain the true character of Juan de Fuca Strait. Vancouver, accompanied by Lieutenant Broughton, left Falmouth on April 1, 1791, and proceeded by way of the Cape of Good Hope to Australia, where he carefully surveyed part of the south-west coast, especially King George's Sound, whose value as a harbour he pointed out. He next made for Dusky Bay, New Zealand (which he was the first properly to explore), and thence sailing north-east, discovered Oparo islet (27° 36′ S.; 144° 12′ W.), and on Dec. 30 reached Tahiti, where he was again joined by Broughton, who meanwhile had discovered Chatham island.

After staying about three weeks at Tahiti and several weeks at the Hawaiian Islands, Vancouver on April 18, 1792, sighted the west coast of North America (California, then known as New Albion) in 39° 27′ N. He examined the coast up to 52° 18′ N. with minute care, surveying all inlets, discovering the Gulf of Georgia, and circumnavigating Vancouver Island.

After another visit (Feb.–March 1793) to the Hawaiian Islands, in whose races and affairs he took great interest, Vancouver resumed his exploration of the American coast in April, surveying north to 56° N., and south (past the Spanish Californian settlements) to 35° N.

During a fresh stay at the Hawaiian Islands (Jan.–March 1794) Vancouver accepted their submission to Great Britain, but his annexation seems never to have been officially ratified. Quitting the group again in March 1794, Vancouver sailed, by Chernigov Island and Kodiak Island, to Cook's inlet, which was now proved to be no river. After a fresh survey of much of the coast north of San Francisco, Vancouver set out homewards via Cape Horn and St. Helena in Oct. 1794. On the way he made a careful examination of Cape St. Lucas, the southern point of Lower California, the Galapagos Islands and some other points.

Vancouver reached the Thames on Oct. 20, and immediately set about the preparation of his narrative, but he died at Petersham in Surrey on May 10, 1798, before he had completed his task. His brother John, assisted by Captain Puget, published the complete record in 1798.

See *A Voyage of Discovery to the North Pacific Ocean and round the World . . . in 1790–95 . . . under Captain George Vancouver*, 3 vols. (1798), with an atlas of maps and plates

VANCOUVER, British Columbia, third city of Canada and its chief port, situated on the south side of Burrard inlet, had a population of 117,217 in 1921, and of 344,833 in 1931 (including annexations). The climate is equable and mild, July mean temperature 70° F. and January 33°. The growth of the city dates from the coming of the Canadian Pacific railway in 1885, and the increasing Oriental trade and the shipping of wheat to Europe by way of the Panama canal revolutionized the status of the port. In 1948 the tons (register) of shipping entered were 19,922,032 as compared with Montreal 7,226,441. The wheat storage capacity of the port reaches 18,716,500 bu. (Montreal, 15,162,000), and the whole crop of Alberta can be handled. The export trade is particularly active when the Great Lakes ports are closed by ice. Timber, canned and salt fish, flour and apples are other important articles of export. Industrial plants include a number of foundries, fish canning and curing and oil works, shingle, saw, paper and pulp mills, sugar refineries, breweries and shipbuilding yards.

The 35-ft. harbour, controlled after 1935 by the National Harbour board (replacing the local Harbour commission), is one of the finest natural harbours in the world, and at mid-century had 28 piers, 75 miles of railway and 31,436 ft. of berthing. The port is a terminus of the Canadian Pacific and Canadian National railway systems, and of the British Columbia Electric railway company's line.

North Vancouver, on the north shore of Burrard inlet nearly 2 mi. from the centre of the city, had a population of 15,579 in 1951, and is connected by Lion's Gate motor toll bridge and a railway bridge with Vancouver proper. Point Grey, a residential suburb, was annexed to the city, and contains the University of British Columbia, which replaced the British Columbia branch of McGill university. The municipality of West Vancouver adjoins North Vancouver.

Vancouver has an airport located on Sea Island 8 mi. from the city as the terminus of the Trans-Canada main line. (C. Cy.)

VANCOUVER, a city of southwestern Washington, U.S., at the head of deep-water navigation on the Columbia river (there crossed by the interstate highway bridge), 8 mi. N. of Portland, the county seat of Clark county. It is on federal highways 99 and 830; and is served by the Great Northern, the Northern Pacific, the Spokane, Portland and Seattle and the Union Pacific railways, motorbus lines and ocean and river steamers. The population was 41,664 in 1950 and 18,788 in 1940 by the federal census. It is the trading centre for large lumber and plywood operations, and for a diversified agricultural district noted for its prunes, filberts, walnuts, small fruits, poultry and dairy products. Vancouver is also an important grain-shipping point to eastern and foreign markets. It is the power distribution centre for the Bonneville and Coulee power projects. The main substation is located at the northern city limits. It has a large plant for production of aluminum pig. The manufactures are chiefly lumber and lumber products, plywood, paper, dried and canned fruits, aluminum, abrasives, chemicals, fruit juices and syrups, dairy products, furs, logging machinery, malts and cereal products. The state schools for the deaf and the blind are within the city limits. Also within the city boundary is Vancouver barracks, one of the principal U.S. army posts on the coast (established in 1848), and Barnes General hospital.

Vancouver, the oldest city of Washington, was founded in 1825 by John McLoughlin, chief factor of the Hudson's Bay company, who built a stockade (Fort Vancouver) on a site now included in the military reservation, and it was one of the company's important trading posts until 1846, when it was taken over by the United States. The village became the county seat in 1854 and was chartered as a city in 1889.

VANCOUVER ISLAND, the largest of an archipelago of innumerable islands which fringes the Pacific coast of Canada, and the largest island on the west coast of North America. It extends from 48° 20′ to 51° N., and from 123° to 128° 30′ W., and is thus 285 mi. long and from 40 to 80 mi. wide, with an area of about 12,408 sq.mi. It is bounded on the south by the Strait of Juan de Fuca, and is separated from the mainland by the Strait of Georgia and Queen Charlotte sound. The island was made a British crown colony in 1849 (having previously been held under grant by the Hudson's Bay company), and in 1866 it was united with British Columbia, which had become a crown colony

in 1858, the enlarged crown colony of British Columbia entered the Dominion of Canada as a province in 1871 The seat of the provincial government and chief port of Vancouver Island (pop, 1951, 215,003, including a few adjacent small islands) is Victoria (pop, 1951, 51,331). The coast line of Vancouver Island is generally precipitous The west coast is much broken by bays and inlets, which penetrate far inland Among these may be mentioned the Alberni canal, which is 20 mi long, with a fine harbour at its head, and the city of Port Alberni Nootka sound, 6 mi wide, and sending three arms inland, as well as Clayoquot, Esperanza, Kyuquot and Quatsino canals, also penetrate deeply into the island. The general height of the mountain range on Vancouver Island is from 2,000 to 3,000 ft , Victoria peak is 7,095 ft. high

There are extensive beds of coal, especially on the east coast, which are mined at Nanaimo (pop, 1951, 7,196), Comox, Ladysmith and other points, and there are large iron deposits. Copper and manganese are also mined. Vancouver Island is covered with many dense forests, which yield immense supplies of magnificent timber, constituting with the coal field and fisheries the chief resources of the island. There are some level tracts on the south-east coast, as well as in the narrow, well-watered valleys of the interior, which afford excellent agricultural land on which cereals of all kinds, as well as all the fruits of the temperate zone, flourish, and which are also suitable for raising sheep and cattle The climate of Vancouver Island, especially in the south, is wonderfully mild for the latitude. (*See also* BRITISH COLUMBIA.)

VANDALS, a term used by early writers only as a collective designation for a group of Teutonic tribes including, according to Pliny, the Burgundians and the Goths The Vandals as a separate people figure in the earliest legends both of the Goths and the Lombards, and first came into contact with the Romans during the Marcomannic War In the time of Aurelian they invaded Pannonia, and during the reign of Probus we find them fighting in Dacia In the time of Constantine I, according to Jordanes, they suffered a great defeat at the hands of Geberich, king of the Goths, their own king Visimar being killed, and the survivors were allowed by the Romans to settle in Pannonia.

Invasions.—In A D 406 they moved westward, according to some writers at the instigation of Stilicho, who is himself said to have been of Vandal origin, and crossing the Rhine at Mainz proceeded towards Gaul.

Owing to defeat at the hands of the Franks the Vandals could not settle in Gaul and in 409 their king Gunderic led them across the Pyrenees They appear to have settled in Spain in two detachments. One, the Asdingian Vandals, occupied Galicia, the other, the Silingian, Andalusia. The Silingian Vandals were well-nigh exterminated during the next 20 years but their Asdingian brethren marched across Spain and took possession of Andalusia In 428 or 429 the whole nation set sail for Africa, upon an invitation received by their king from Bonifacius, count of Africa, who had fallen into disgrace with the court of Ravenna Gunderic was now dead, and supreme power was in the hands of his bastard brother Gaiseric who was for 50 years the terror of Constantinople and Rome. Probably in the month of May 428, he assembled all his people on the shore of Andalusia, and numbering the males among them from the greybeard down to the newborn infant found them to amount to 80,000 souls. The nation was transported to Africa in ships supplied by Bonifacius Although he soon returned to the Imperial allegiance only three cities of Roman Africa—Carthage, Hippo and Cirta—remained untaken by the Vandals by May 430. At length (Jan 30, 435) peace was made between the emperor Valentinian III. and Gaiseric. The emperor was to retain Carthage and the small but rich proconsular province in which it was situated, while Hippo and the other six provinces of Africa were abandoned to the Vandal. Gaiseric observed this treaty no longer than suited his purpose. On Oct. 19, 439, he suddenly attacked and took Carthage. The Vandal occupation of this great city, the third among the cities of the Roman empire, lasted for 94 years Gaiseric seems to have counted the years of his sovereignty from the date of its capture. Henceforward he made of Carthage a pirate's stronghold, whence he issued forth, like the Barbary pirates of a later day, to attack, as he himself said, "the dwellings of the men with whom God is angry," leaving the question who those men might be to the decision of the elements. Almost alone among the Teutonic invaders of the empire he set himself to form a powerful fleet, and was probably for 30 years the leading maritime power in the Mediterranean Gaiseric's celebrated expedition against Rome (455), undertaken in response to the call of Eudocia, widow of Valentinian, was only the greatest of his marauding exploits He took the city without difficulty, and for 14 days, in a calm and business-like manner, emptied it of all its movable wealth Eudocia and her two daughters were carried into captivity.

Empire and Defeat.—There does not seem to be in the story of the capture of Rome by the Vandals any justification for the charge of wilful and objectless destruction of public buildings which is implied in the word "vandalism" It is probable that this charge grew out of the fierce persecution which was carried on by Gaiseric and his son against the Catholic Christians The bishops were almost universally banished, and the congregations were forbidden to elect their successors, so that the greater part of the churches of Africa remained "widowed" for a whole generation In 476, at the very close of Gaiseric's life, by a treaty concluded with the Eastern emperor, the bishops were permitted to return There was then a short lull in the persecution; but on the death of Gaiseric (477) and the accession of Hunneric it broke out again with greater violence than ever

On the death of Hunneric (484) he was succeeded by his cousin Gunthamund, Gaiseric having established seniority among his own descendants as the law of succession to the throne. Gunthamund (484–96) and his brother Thrasamund (496–523), though Arians, abated some of the rigour of the persecution, and maintained the external credit of the monarchy. On the death of Thrasamund, Hilderic (523–31), the son of Hunneric and Eudocia, at length succeeded to the throne He adhered to the creed of his mother rather than to that of his father; and, in spite of a solemn oath sworn to his predecessor that he would not restore the Catholic churches to their owners, he at once proceeded to do so and to recall the bishops. Hilderic, elderly, Catholic and timid, was very unpopular with his subjects, and after a reign of eight years he was thrust into prison by his cousin Gelimer (531–534).

The wrongs of Hilderic, a Catholic, with the blood of the emperor Theodosius in his veins, afforded to Justinian a long-coveted pretext for overthrowing the Vandal dominion. A great expedition under the command of Belisarius reached Africa in the beginning of Sept. 533 A large force of Vandals was then occupied in Sardinia under Gelimer's brother Tzazo, and the landing of Belisarius was entirely unopposed. He marched rapidly towards Carthage and on Sept 13, defeated Gelimer at Ad Decimum, 10 m. from Carthage. Next day he entered Carthage and ate the feast prepared in Gelimer's palace for its lord Belisarius, however, was too late to save the life of Hilderic, who had been slain by his rival's orders as soon as the news came of the landing of the imperial army. On the return of Tzazo from Sardinia a force was collected considerably larger than the imperial army, but the Vandals were defeated and Gelimer took to flight He took refuge in a mountain fortress called Papua on the Numidian frontier, and there, after enduring great hardships in the squalid dwellings of the Moors, surrendered to his pursuers in March 534. The well-known stories of his laughter when he was introduced to Belisarius, and his chant, "Vanitas vanitatum," when he walked before the triumphal car of his conqueror through the streets of Constantinople, probably point to an intellect disordered by his reverses and hardships. The Vandals who were carried captive to Constantinople were enlisted in five squadrons of cavalry and sent to serve against the Parthians under the title "Justiniani Vandali." Four hundred escaped to Africa and took part in a mutiny of the imperial troops, which was with difficulty quelled by Belisarius (536). After this the Vandals disappeared from history. The overthrow of their kingdom undoubtedly rendered easier the spread of Saracen conquest along the northern shore of Africa in the following century. (F. G. M. B ; T H)

VANDAMME, DOMINIQUE RENÉ, COUNT (1770–1830), French soldier, was born at Cassel, near Dunkirk, on Nov 5, 1770 He enlisted in the army in 1786, served in Martinique in 1788 and on returning to France entered into the Revolutionary movement, raising a company of light infantry. He was promoted and after Hondschoote he was made general of brigade, serving in the Low Countries (1794), on the Rhine (1795) and in Germany (1796) In 1799 he was promoted general of division, and served in Holland, Germany and Switzerland He was a devoted servant of Napoleon. In 1805, for his leadership at Austerlitz, he was given the Grand Eagle of the Legion of Honour, and in 1806–07 he commanded a small corps of the *Grande Armée* which reduced the Silesian fortresses. In 1808 he was made count of Unebourg. In 1809 he served in the Eckmuhl campaign, but in 1812, while commanding the Westphalian contingent he quarrelled with King Jerome Bonaparte and returned to France He returned to the army in 1813, but his corps, sent against the line of retreat of the Allies at the battle of Dresden, surrendered at Kulm (*See* NAPOLEONIC CAMPAIGNS) At the end of the war he was forbidden to enter Paris When Napoleon returned Vandamme joined him and was made a peer of France and placed at the head of the 3rd corps in the army of the north (*See* WATERLOO CAMPAIGN, 1815) The Restoration first imprisoned and then exiled him. He died at Cassel on July 15, 1830

VANDERBILT, CORNELIUS (1794–1877), American capitalist, was born near Stapleton, Staten island, N Y, on May 27, 1794 At the age of 16 he bought a sailboat, in which he carried farm produce and passengers between Staten island and New York, in 1813 carrying supplies to fortifications in New York harbour and the adjacent waters In 1817–29 he was a captain on a steam ferry between New York and New Brunswick. He developed an extensive carrying trade along the coast in a fleet which became so large as to win for him the popular designation of "Commodore." In 1849 he got from the Nicaraguan Government a charter for a route across the isthmus. In 1855–61 he operated a freight and passenger line between New York and Havre. In 1857–62 he sold his steamships and turned his attention to railways In 1857 he became a director, and in 1863 president, of the New York and Harlem Railway

He then acquired a controlling interest in the Hudson River Railway, of which he became president in 1865, and in 1868 he became president of the New York Central (between Albany and Buffalo), which in 1869 he combined with the Hudson River Road, under the name of the New York Central and Hudson River Railroad. His acquisition of the Lake Shore and Michigan Southern Railway in 1873 established a through line between New York and Chicago. At the time of his death (in New York city on Jan. 4, 1877) he controlled the New York Central and Hudson River, the Lake Shore and Michigan Southern, the Harlem, and the Canada Southern railways, and had holdings in many others He endowed Vanderbilt university.

His eldest son, WILLIAM HENRY VANDERBILT (1821–1885), was born in New Brunswick, N.J., on May 8, 1821. He was a clerk in a New York banking house from 1839 to 1842 In 1860 he was appointed receiver of the Staten Island Railway, of which he was elected president in 1862, and which he brought into connection with New York by means of a line of ferry-boats. He became vice president of the Hudson River Railway in 1865, vice president of the New York Central and Hudson River Railroad in 1869, and president in June 1877, succeeding his father as president of the Lake Shore and Michigan Southern, the Canada Southern, and the Michigan Central railways. He died in New York city on Dec. 8, 1885.

William Henry's eldest son, CORNELIUS (1843–1899), became assistant treasurer of the Harlem Railway in 1865, and treasurer in 1867; in 1877, after the death of his grandfather, he was elected first vice president of the New York Central, and in 1878 became treasurer of the Michigan Central and vice president and treasurer of the Canada Southern In 1883 he became chairman of the boards of directors of those two systems

VANDERGRIFT, a borough of Westmoreland county, Pennsylvania, U S A , on the Kiskimminetas river and the Pennsylvania railroad, 30 mi. N E of Pittsburgh. Pop (1950) 9,581 and 10,725 in 1940 It is in a farming and coal-mining region, which also has gas wells; and the borough manufactures sheet steel, steel castings and other commodities

VANDERLYN, JOHN (1776–1852), American artist, was born in Kingston, N Y., on Oct. 15, 1776 He was employed by a print-seller in New York, and was first instructed in art by Archibald Robinson (1765–1835), a Scotsman who was afterwards one of the directors of the American Academy He copied some of Gilbert Stuart's portraits, including one of Aaron Burr, who placed him under Gilbert Stuart as a pupil In 1796 Vanderlyn went to Paris, and in 1805 to Rome, where he painted his picture of "Marius amid the Ruins of Carthage," which was shown in Paris, and obtained a gold medal there This success caused him to remain in Paris for seven years, during which time he prospered greatly In 1812 he showed a nude "Ariadne" (engraved by Durand, and now in the Pennsylvania Academy), which increased his fame. When Aaron Burr fled to Paris, Vanderlyn was for a time his only support. Vanderlyn returned to America in 1815, but did not meet with success; he worked very slowly, and neither his portraits nor various panorama which he exhibited brought him any considerable financial return. In 1842, through friendly influences, he was commissioned by Congress to paint "The Landing of Columbus" for one of the panels in the rotunda of the Capitol at Washington Going to Paris, he employed to assist him a French artist, who, it is said, did most of the work. He died at Kingston, N Y , on Sept 23, 1852.

VAN DER STAPPEN, CHARLES (1843–1910), Belgian sculptor, was born in Brussels, September 1843 His first contribution to the Brussels Salon was "The Faun's Toilet" of 1869, and after this he soon became recognized as the leader, along with Paul de Vigne, of the new Belgian school of sculpture which, while remaining true to life, drew inspiration from Greek art and the Italian renaissance. Examples of Van der Stappen's decorative sculpture are seen in the decoration on the Palais des Postes, Brussels (1872), the pediment "Orchestration" for the Conservatoire de Musique, and the noble bronze group, "The Teaching of Art," on the façade of the Palace of Fine Arts, Brussels. He also executed the statues for the Alhambra Theatre and the caryatides for the house of the architect M. de Curté (1874). His best-known monuments are those to "Alexandre Gendebien" (1874) and "Baron Coppens," at Sheel (1875).

VANDERVELDE, EMILE (1866–1938), Belgian statesman, was born on Jan 25, 1866 at Ixelles near Brussels. He studied law at Brussels university and in 1885 took his doctorate in social science. In the following year he joined the Belgian Labour Party and soon became its acknowledged leader. He first entered parliament in 1894 as Socialist member for the Charleroi constituency, but after 1900 was returned continuously by Brussels In the chamber he achieved both influence and prestige and played a prominent part in the struggle to attain universal suffrage, a struggle which resulted in more than one national general strike. On the outbreak of World War I, Vandervelde devoted himself to the problems of national defence, the liberation of his invaded country, and in Aug. 1914 was summoned to join the Government

as minister of state, later becoming member of the cabinet. At the time of peace negotiations and the signing of the Versailles treaty, he used his influence to obtain the insertion of labour clauses, relating especially to the eight-hour day As minister of justice in the Liberal-Catholic-Socialist cabinet formed after the war, Vandervelde effected great humanitarian and scientific reforms in the prison system. After the important successes achieved by the Labour party in the general elections of 1925 he entered the Socialist-Catholic coalition cabinet as minister for foreign affairs and played an important part in negotiating the Locarno pact in 1925, which he signed on behalf of Belgium. He retained the portfolio of foreign affairs in Jaspar's ministry of "national unity" He came to be regarded abroad as well as in Belgium as essential in Belgian foreign policy, partly because of his success at Locarno and the high esteem in which he was held by his foreign colleagues at Geneva. But he was constantly subjected to criticism because of his genuine internationalism, and early in 1927 he had some difficulty in soothing his non-Socialist critics In internal politics he fought for a reduction of the term of military service to six months and thorough reorganization of the army system This attitude of the Socialist members of the Jaspar cabinet was the immediate cause of its fall. Vandervelde was minister without portfolio, 1935–36, and minister of public health, 1936–37.

Considered by some to be the most powerful Socialist orator in the French language since Jaurès, Vandervelde played a very conspicuous role in all the international Socialist congresses after the beginning of the 20th century. In 1924 he was made professor of political economy at the University of Brussels.

Bibliography.—Among his works are *Le socialisme en Belgique*, with J Destrée (1898), *Le collectivisme et l'évolution industrielle* (1900, trans by R P Farley, 1907); *Essais sur la question agraire en Belgique* (1902); *La Belgique et le Congo* (1911); *La grève générale en Belgique, avril 1913* (1914), *Le socialisme contre l'état* (1918), *Réalisations socialistes* (1923); *Le parti ouvrier belge, 1885–1925* (1925)

VAN DE VELDE or Vandevelde, name of a family of Dutch artists active during the 17th century. The most notable members were:

Adrian van de Velde (1636–1672), landscape and animal painter, born at Amsterdam in Nov. 1636. He was a son of Willem van de Velde I (*see* below) He was trained in the studio of Jan Wynants, where he made the acquaintance of Philip Wouwerman, who seems to have helped him with his studies of animals He was employed by his master to introduce figures into his landscapes, and he rendered a similar service to Hobbema, Ruysdael, Verboom and others His favourite subjects are scenes of open pasture land with sheep, cattle and goats, admirably drawn and with clear, silvery colouring. He also painted a few excellent winter scenes with skaters, and executed a Passion series for the Spinhuiskerk at Amsterdam (now in the parsonage of the Augustinian church "De Ster"). In addition to his paintings, of which De Groot catalogued 387, he made about 30 etchings, they are distinguished by a pleasing tonality and by delicacy and certainty of touch. He died at Amsterdam on Jan. 21, 1672.

Jan van de Velde II (1593–after 1641), an engraver who excelled in portraiture, genre and biblical scenes, and views of towns and landscapes. There are 429 engravings by him extant. He was a brother of Willem van de Velde I (*see* below).

Willem van de Velde I (1611–1693), a celebrated draftsman of ships, born at Leyden. He was employed by the Dutch government to depict sea fights, and for that purpose accompanied the Dutch fleet during the war with England He went to England in 1672 with his son, Willem van de Velde II (1633–1707), a native of Amsterdam, and pupil of his father and of the marine painter Simon de Vlieger. Both artists were employed by Charles II, and afterward by James II, at a salary of £100 each "for taking and making draughts of sea-fights," the son's part being to reproduce in colour the drawings of the father. Willem the elder died at Greenwich in 1693. His epitaph in St. James's church records that he was "a painter of sea-fights to their Majesties." Willem the younger was made court painter in 1677. His first works represent views off the coast of Holland, with Dutch shipping. He died in London on April 6, 1707.

VAN DE VELDE, HENRY CLEMENS (1863–), Belgian architect, was born at Antwerp on April 3, 1863, and studied at the Antwerp academy, under the painter Charles Verlat and in Paris under Carolus Duran He turned to applied art about 1891–93 after "discovering" William Morris and the English arts and crafts movement. The furniture he designed for his own house at Uccle, near Brussels (1894–95), though exhibiting *art nouveau* forms, had its structure clearly emphasized by "directional" ornament, the interior was an early example of the tendency to dispense with strict room partition The four rooms he designed for the Paris art galleries of S Bing in 1896 profoundly influenced French design From 1902 to 1914 Van de Velde was director of the Weimar Kunstgewerbliches Institut, for which he designed a new building in 1906 He later became connected with the *Deutsche Werkbund* and in 1914 designed the theatre at the *Werkbund's* Cologne exhibition. He was director of the Brussels Institute des Arts Decoratifs, 1926–43, and professor at Ghent university, 1926–36, of whose library he was associate architect (1938). He supervised restoration work for the Belgian government after World War II

VAN DOREN, CARL CLINTON (1885–1950), U.S author, editor and critic, was born on a farm near Hope, Ill , Sept. 10, 1885 He graduated from the University of Illinois in 1907 and received his Ph D from Columbia university in 1911. His first book, a biography of Thomas Love Peacock, was also published in 1911. He taught English at Columbia from 1911 to 1930. From 1917 to 1921 he was managing editor of the *Cambridge History of American Literature*.

From 1919 to 1922 he was literary editor of the *Nation*, and from 1922 to 1925 literary editor of *Century Magazine*.

His writings ranged through surveys of literature to novels, biography and criticism. In 1939 he received a Pulitzer prize for his biography *Benjamin Franklin* (1938) His works included *The American Novel* (1921, revised 1940), *Contemporary American Novelists* (1922), *American and British Literature since 1890* (1925), in collaboration with his brother, Mark Van Doren, and revised in 1939; *American Literature. An Introduction* (1933), reissued as *What Is American Literature?* (1935). Some of his other important works were *James Branch Cabell* (1925); *Swift* (1930), *Sinclair Lewis* (1933); and his autobiography, *Three Worlds* (1936).

VAN DYCK, SIR ANTHONY (1599–1641), Flemish painter, was born in Antwerp on March 22, 1599 Though the name of Van Dyck is frequently met with in the list of Antwerp painters, Anthony's pedigree cannot be traced beyond his grandparents, who were silk mercers of some standing He was the seventh of 12 children of Frans van Dyck, an Antwerp merchant.

The boy was little over ten when he was apprenticed to Hendrick van Balen, the painter of many delicate little pictures and the master of Snyders. From a document in the state paper office at Brussels, relating to a lawsuit between a picture dealer and an Antwerp churchman, which arose out of the sale, in 1660, of a series of Apostles' heads ascribed to Van Dyck, it appears that, as far back as 1615, Van Dyck had worked independently, with pupils of his own, and that his pictures were valued by artists and amateurs.

Early Works.—Before he was 19 (Feb. 1618) Van Dyck became a full member of the Antwerp guild of painters,' and some idea of his ability at the time may be gained from the excellent portraits of an old lady and gentleman, formerly ascribed to Rubens, in the Dresden gallery But the same admiration cannot be accorded to the earliest religious composition known to have been painted by him, "Christ Falling under the Cross," in St. Paul's at Antwerp. At first sight it seems also that with him, as with most other Flemish painters of the period, every conception, whether sacred or profane, needed to be cast in the mould of Rubens. It would be too much, however, to assert that Van Dyck at this time stood under the guidance of that master, their association, indeed, does not seem to have begun until 1619, and Bellori (1672), who got his information from Sir Kenelm Digby, Van Dyck's bosom friend, related that he was first employed in making drawings (probably also chiaroscuros) for the use of the great master's engravers, and that

among works of the kind one of the first was the "Battle of the Amazons" (1619).

In 1620 Van Dyck was working with Rubens, for on March 20, in making arrangements with the Antwerp Jesuits for the decoration of their church, the master is allowed to avail himself of his pupil's assistance, and obtains for him the promise of a picture. Van Dyck left for England in the autumn of 1620. There is evidence in the order books of the exchequer of Van Dyck's presence in London till the end of February 1621 What Van Dyck did in London is not known That he was at the time a portrait painter of the rarest merit may easily be seen from the portrait of "Van der Geest" in the National Gallery (London), and from his own likenesses of himself when still quite young and beardless, in the National Gallery, in the Pinakothek at Munich and, as Paris, in the Wallace Collection.

Residence in Italy.—Van Dyck's next journey was to Italy. He left Antwerp on Oct. 3, 1621, and arrived at Genoa on Nov. 21. Though Van Dyck unquestionably first became acquainted with the masterpieces of the great Venetian colourists in Rubens's *atelier*, most of the pictures which were formerly ascribed to his earliest period probably date from the years of his Italian journey. In fact, studies for some of them can be found in the Chatsworth sketch-book. Among these early works are the "Martyrdom of St Peter" (Brussels), the "Crowning with Thorns" (Berlin), and the "Betrayal of Christ" (Madrid, a replica formerly Lord Methuen's is now in America). A sketch of the same subject is at Doughty House, Richmond.), "St. Martin dividing his Cloak" (Windsor Castle),—a magnificent production On a reduced scale, and with the omission of two or three figures, the "St. Martin" at Saventhem church is a reproduction of the picture at Windsor Castle

With the exception of a short visit to Antwerp at the time of his father's death in 1622, Van Dyck spent the next five years in Italy. There can be no doubt as to the great influence exerted by the works of Titian, Paul Veronese and other masters of the Venetian school in the development of his genius, still the individuality of the painter remains a striking feature of what may be termed his Italian works, especially portraits Their peculiar character seems to originate even more in the stateliness of his sitters than in any desire to follow individual predilection or prevailing fashion. It is difficult to trace with certainty the course of the artist's travels in Italy. He made a prolonged stay at Venice; at Rome, he resided with Cardinal Guido Bentivoglio, who had been papal nuncio in Flanders from 1607 to 1617. For this patron were painted several important works, the most renowned being the prelate's own portrait, now in the Pitti Palace at Florence Another work was a "Crucifixion" spoken of by Bellori —but which cannot be identified with certainty among the many replicas of the subject existing at Antwerp, Genoa, Vienna and Munich. He also painted religious subjects and portraits, such as the portrait of Duquesnoy, better known as Fiammingo, the famous sculptor, and those of Sir Robert Shirley and his wife, in Persian attire. In the company of Lady Arundel he travelled to Turin, but he was eager to reach Genoa; here he probably painted the portraits of Luke and Cornelis de Wael, now in the Pinacoteca Capitolina at Rome (a monochrome replica at Cassel). Genoa can still boast of a good number of his most attractive productions, portraits of the beautiful ladies and haughty cavaliers of the noble houses of Doria, Brignole Sale, Pallavicini, Balbi, Cattaneo, Spinola, Lommelini and Grimaldi It would scarcely be possible to speak too highly of such works as the portrait of the lady in white satin and the Durazzo children at the Durazzo Palace, the Balbi children from Panshanger now lent to the National Gallery, the Marchesa Balbi, formerly at Dorchester House, the equally beautiful portraits of the Lommelini and of the knight in black armour, buff jacket and boots in the Scottish National Gallery at Edinburgh, or the Marchesa Brignole Sale (Warwick Castle). Van Dyck's Genoese portraits are remarkable for their richness of tonality and what might be called royal splendour, perhaps never before attained in works of the kind. This we may suppose to have had its origin, not only in his recent study of Titian, but also in decorative necessities—the size of the palatial galleries and the rich hues of the Genoese velvets, on which these portraits were to find their place, obliging the painter to find a most uncommon strength of contrast. In Italy, more over, he found those gorgeous backgrounds—flowing draperies, beautiful gardens, ornamental pillars, marble terraces and balustrades—which elsewhere must be regarded as fictions merely Here, finally, he was called upon to paint some of his grandest equestrian portraits, and the often recurring grey steed with flowing mane (an admirable study of which belongs to Lord Brownlow) was first employed for the portrait of Antonio Giulio Brignole (still at Genoa). As with Rubens, Titian seems to have been paramount in Van Dyck's regard. We know he possessed copies of the master's best works, and several little sketches in the British Museum and in the Chatsworth sketch-book bear proof of his devout study of the great Venetian Some of Van Dyck's earlier paintings, religious and mythological—the "Tribute Money" (Palazzo Bianco), "Holy Family" (Turin), "Virgin and Saints" (Louvre), "Virgin" (Grosvenor House), are certainly Titianesque in the extreme.

In 1624 Van Dyck sailed from Genoa to Palermo and there painted several persons of rank, including the viceroy, Emmanuel Philibert of Savoy. While in Sicily he became acquainted with the painter Sofonisba Anguisciola (or Angussola), who was then ninety-six years of age and blind; and he was wont to say that he had received more valuable information from a blind woman than from many a seeing man. There is a "Virgin and Child" by Van Dyck at S. Caterina in Palermo, and a "Virgin and Child with Saints" in the same city. Bellori tells us that plague compelled him to leave abruptly, taking with him an unfinished picture of St Rosalia, completed in Genoa. The composition was repeated in Antwerp for the Bachelor's Brotherhood, a picture now in Vienna Van Dyck most probably remained in Genoa till 1626, and here in all likelihood he painted the De Jodes, father and son, the celebrated engravers, who are represented together in a masterly portrait in the Capitol at Rome

Traversing the Mont Cenis pass, Van Dyck stopped at Aix with Peiresc, the famous scholar and friend of Rubens, and probably proceeded straight to Antwerp. His beautiful portrait of Langlois, the Paris print-seller, from which it was conjectured that he spent some time at Paris, was unquestionably painted in Genoa By March 3, 1628 he was back at Antwerp. One of his sisters had died in a convent the year before, and he now made a will in favour of Susan and Isabella, two other sisters, also nuns That Van Dyck was in Antwerp on May 18, is proved by a letter from Lord Carlisle to Buckingham (Sainsbury, cili).

The Antwerp Period.—Great as may have been the strength of Italian reminiscence, from the moment Van Dyck again trod Flemish soil the influence of Rubens became predominant Among the earliest works after his return to Antwerp is the "Crucifixion," given to the Dominican nuns, in accordance with the wish expressed by the painter's dying father, and now in the Antwerp museum. The figures are life-size, and at the foot of the cross, besides a weeping angel, are St. Catherine of Siena and St Dominic Neither in type nor in general effect does it suggest the master's immediately preceding works. As a new feature we observe a kind of elegance, not entirely free from mannerism, which is often conspicuous with Van Dyck even when the technical excellence commands our warmest admiration Inspiration was far more limited with Van Dyck than with Rubens. His delicate nature led him to restrain his conceptions within the bounds of an academic evenness. To Van Dyck's second—more justly speaking third—manner belong some of his best religious works. The "Crucifixion" in the cathedral at Mechlin is termed by Sir Joshua Reynolds one of the finest pictures in the world. Still finer are the two works painted for the Antwerp Jesuits and now at Vienna—"The Mystic Marriage of the Blessed Herman Joseph" and "St. Rosalia Crowned by the Infant Saviour." To this period likewise belong the celebrated "Elevation of the Cross" at Courtrai and the "St. Augustine in Ecstacy," in the church of the Jesuits at Antwerp; the general effect of this last, according to Reynolds, is inferior to that of the beautiful engraving by De Jode, and also to the earl of Northbrook's mag

nificent sketch. Van Dyck's Flemish portraits indicate, technically speaking, a further step towards perfection. The darkness of the Genoese portraits has vanished, broad daylight now freely illuminates the model, and such works as the portraits of Francisco de Moncada (Louvre) and of the Count de Bergh (Prado) are perhaps as close to material excellence as any painting could be. The full-length likenesses of Philip Le Roy (1630) and his wife (1631) (Wallace Collection) and of Mary Louisa of Tassis (Prince Liechtenstein, Vienna) deserve to rank among the most beautiful portraits ever painted. The "Snyders" at Castle Howard is regarded by Waagen as not inferior to the most celebrated Raphaels, Titians or Holbeins; and of almost equal excellence are the "Wife of Colin de Nole" in the Munich gallery, the "Lady and her Daughter" at the Louvre, and the "Lady in Black" at Cassel

Rapidly rising to honour and wealth, Van Dyck shared with Rubens the official title of court painter, and he painted numerous portraits of the infanta in her monastic garb (Paris, Vienna, Turin, Parma, etc.). When Marie de Medici fled from France to Brussels (1631), she several times commissioned Van Dyck to paint her likeness, as well as those of Gaston of Orleans and his wife Margaret of Lorraine, and several of the personages of their court. From Gerbier's letters we learn that Van Dyck at this time was contemplating a journey to England, and desired commissions from the infanta and the queen of France to take over their portraits as presents for the king and royal family He soon travelled to The Hague to paint the prince and princess of Orange and their son. Early in 1632 Constantine Huygens, who was then living at The Hague, inscribes in his diary, "pingor a Van Dyckio." When, in March, Van Dyck sailed for England, he took these portraits with him.

Settles in London.—Gerbier's letters show that the king had personally desired his presence in London. As early as March 1629 Endymion Porter had been commissioned to order a picture from Van Dyck, "Rinaldo and Armida." The canvas, now belonging to the duke of Newcastle, is one of the master's finest creations Besides the title of painter in ordinary, and an annual pension of £200, he received a knighthood (July 5, 1632). He rapidly achieved popularity, and, as Walpole says, his works are so frequent in England that to most Englishmen it is difficult to avoid thinking of him as their countryman.

Few artists, whether in England or elsewhere, have more richly endowed their models with distinction of feature and elegance in bearing. Charles I. and Henrietta Maria, although pictured by several other painters, are known to posterity almost exclusively through Van Dyck, because of a particular power of expression and bearing which, once seen, it is impossible to forget. The artist was given a summer residence at Eltham Palace, and was frequently visited by the king at his studio at Blackfriars. Portraits now followed each other with great rapidity His mode of living and his love of pleasure sufficiently explain his great need of money. During his first year in England he painted the king and queen a dozen times. The first of these noble portraits is the admirable full-length of Charles I, with the queen and their two eldest children, at Windsor Castle. The style he adopted in England is generally termed his third manner; we might better say his fourth, as he already had a very particular style before he set out on his Italian journey. De Piles gives us some account of Van Dyck's methods at this period of his career He began with a small sketch on grey paper with black and white chalks, or a monochrome in oils. This study was passed on to assistants in order to be copied on the required scale. When the clothes were sufficiently advanced by the pupils from those sent by the model, as well as the background and accessories, the master was enabled in a few sittings of an hour each to complete the work. Van Dyck excelled in painting the hands; he is said to have kept special models for this part of his work. It need hardly be said that a system of this kind, although employed by Rubens for his larger creations, was exceedingly ill adapted to portrait painting. In Van Dyck's later productions we too often detect marks of haste, as if the brush were becoming a mere implement of trade.

Visit to the Netherlands.—Nearly the whole of 1634 and 1635 were spent by Van Dyck in the Netherlands, whence his brother, an Antwerp priest, had been called over by the queen to act as her chaplain. The archduchess died Dec. 1, 1633, and Van Dyck wished to get his official title renewed by her successor, Ferdinand of Austria, brother of Philip IV. On the arrival of the new governor Van Dyck was immediately called upon to paint his likeness (Madrid gallery). Another portrait of Ferdinand on horseback belongs to Mr Mainwaring, Oteley Park, Shropshire. The most important of Van Dyck's works, at any rate as a portrait painter, belong to this period. The picture representing in life-size the members of the Brussels corporation, which was destroyed by fire during the siege of 1695, is spoken of with intense admiration by several writers Bullart, for instance, is very enthusiastic about its fine colour and life-like qualities. Among the religious paintings of undisputed excellence belonging to the same period are the "Adoration of the Shepherds" in the church at Termonde, and the "Deposition," where the body of Christ rests upon the lap of the Virgin, in the Antwerp museum Among the portraits are the admirable full-length of Scaglia, the king's frequent agent in the Netherlands (formerly at Dorchester House), the equestrian portrait of Albert of Arenberg (Holkham Hall), and a portrait of the same nobleman on foot, in the black velvet Spanish dress with golden chamberlain's key (Althorp), an admirable half-length of a lady in black (Vienna gallery), and above all the grandiose picture in which John of Nassau is represented at full-length, with his wife and children.

Returns to London.—After being chosen honorary president of the Antwerp gild of St. Luke, Van Dyck returned to London before the end of 1635 In spite of the vast number of his later portraits, some of them deserve to be ranked among the most celebrated of his productions The group of three English royal children in the gallery at Turin (1635), the portraits of Charles I. in the Louvre and in the National Gallery, London, the picture of the Pembroke family at Wilton House, Sir George and Sir Francis Villiers at Windsor and in the National Gallery and the earls of Bristol and Bedford, at Althorp, all belong to the years following the master's return from the Netherlands.

He married, about the end of 1639, Lady Mary Ruthven, daughter of Sir Patrick Ruthven and granddaughter of the earl of Gowrie. There are several portraits of her by her husband, the most important being in the Munich gallery, in which she is represented in white satin, playing on the violoncello There is a capital engraving of her by Bolswert. In another picture (J. C. Harford, London) a handsome lady said to be Mary Ruthven, is represented as "Herminia Putting on Clarinda's Armour." There can be no doubt as to the model having been Margaret Lemon, a celebrated beauty, whose portrait was engraved by W. Hollar and J. Morin and painted by Van Dyck at Hampton Court. She was the most beautiful and celebrated, though far from being the only mistress of Van Dyck.

When the news of Rubens's death reached London (June 1640) Van Dyck contemplated a return to his native country, and a letter from Ferdinand of Austria to Philip IV. speaks of his intended journey to Antwerp on St. Luke's Day (Oct. 18) Rubens had left unfinished a series of paintings commanded by the king of Spain, and Van Dyck had been thought of to give them the finishing touch But he refused. It was then agreed that he should paint an independent canvas destined to complete the series Whether Van Dyck found it possible to work during his short stay in the Netherlands is doubtful It has been suggested that Van Dyck's principal object in travelling to the continent was to be entrusted with the decoration of one of the galleries of the Louvre. Unfortunately the great painter was thwarted in his aspirations. His health was beginning to fail.

The portraits of William II. of Orange and the Princess Mary, now in the museum at Amsterdam, are the last Van Dyck painted in England. Of works dated 1639 the portrait of the Countess of Portland (Darmstadt) is a fine example; and to the same year belongs a full-length portrait of Arthur Goodwin at Chatsworth. Van Dyck sailed in September, and probably spent some time with his Antwerp friends. Early in November he reached Paris, but on Nov. 16 he was compelled to resign his commissions

on account of the state of his health. Scarcely three weeks later (Dec. 9, 1641) he died at his residence at Blackfriars Van Dyck was buried in old St. Paul's, where a Latin inscription was placed on his tomb by Charles I.

An elegy in Cowley's *Miscellanies* speaks, not only of the painter's talent, but of his amiable disposition. We may perhaps point to the coincidence that a Mrs Cowley is in Van Dyck's will (of Dec 1) named guardian of his child, Justinana Anna, born only eight days before her father's death. The painter had in the Netherlands an illegitimate daughter, Maria Theresia, who was entrusted to his sister, and to whom he bequeathed £4,000 Lady Van Dyck became the second wife of Sir Richard Pryse of Gogerddan in Cardiganshire. She was dead in 1645. Justinana Van Dyck, who was married when scarcely twelve years old to Sir John Stepney of Prendergast, painted a "Crucifixion," with four angels receiving Christ's blood in chalices After the Restoration a pension of £200 for life was granted to Justiniana Van Dyck, who died before 1690

Properly speaking, Van Dyck cannot be said to have formed a school He was followed to London by some of his earlier collaborators, and there soon met a considerable number of others Jan van Reyn, David Beek, Adrian Hanneman, Mathew Merian, John Bockhorst (Lang Jan), Remy van Leemput and Peter Thys were foremost among foreigners, Henry Stone and William Dobson among Englishmen. To their assistance the master owed much; but they are also responsible for the vast number of constantly recurring copies which go by his name It often requires a very discriminating eye to distinguish some of these copies from the original paintings. No school more strikingly reflects the influence of Van Dyck than the British school Stone, Dobson, George Jameson, Robert Walker and Samuel Cooper were the most fortunate of his continuators, and such masters as Reynolds, Gainsborough, Lawrence and Raeburn owe much to their study of his works.

Though Van Dyck's reputation greatly suffered through the numerous copies he allowed his pupils to take from his works, the case is otherwise with engraving: Vorsterman, Pontius, Peter de Jode, P. Balliu and S. Bolswert were seldom more fortunate than when under his guidance. De Jode's "St. Augustine," Bolswert's "Ecce Homo" and "Crucifixion," Vorsterman's "Deposition," and especially Pontius's "Herman Joseph" rank among the masterpieces of the art of engraving. Van Dyck was himself an incomparable etcher. The art of portrait etching, scarcely in existence before his time, reached the highest point of excellence in his work. He etched some 18 plates for a collection of portraits generally called "the Iconography." Such prints as the portraits of Vorsterman, John de Wael, Snyders, Josse de Momper, Adam van Noort, and above all his own effigy, display a manner fresh and personal admirably suited to the medium. Print collectors pay extravagant prices for a first proof taken from the plates engraved by Van Dyck himself. Van Dyck also employed some of the best engravers of his time for this collection of illustrious heads Whether the whole series had been published before 1645 when it was issued by Hendrick is uncertain. Martin van der Enden, whose name appears on some of the plates was probably only a printer, who issued the plates separately as the work proceeded. Hendrick's edition contains 99 plates He used as a frontispiece the portrait of Van Dyck, with the following inscription: *Icones principum, virorum doctorum, &c. &c., numero centum ab Antonio Van Dyck pictore ad vivum expressae elusq. sumptibus aeri incisae*, 1645. Seventeen editions were published, the last in 1759, with 124 plates. Many of the plates are the property of the French Government, and belong to the Chalcographie Nationale in Paris. A relic of great importance is a sketch-book obviously used by the painter in Italy containing but few original compositions and chiefly studies of the Italian masters. This book, once in the possession of Sir Peter Lely, is now at Chatsworth.

LITERATURE.—See W. H. Carpenter, *Pictorial Notices, consisting of a Memoir of Sir Anthony Van Dyck, with a descriptive catalogue of the etchings executed by him* (1844); John Smith, *A Catalogue Raisonné of the Works of the most Eminent Dutch, Flemish, and French Painters*, part iii. (1832); J. Guiffrey, *Antoine Van Dyck, sa vie et son oeuvre* (1882); A Michiels, *Ant. Van Dyck et ses élèves* (1881); I. v. Szwykowski, *A. Van Dycks Bildnisse bekannter Personen* (Leipzig, 1858); Fr Wibiral, *L'iconographie d'A. Van Dyck d'après les recherches de H. Weber* (Leipzig, 1877); Lionel Cust, *Anthony Van Dyck* (1900), an abridgment with emendations, *Van Dyck* (1906), and *A Description of the Sketch-Book by Sir Anthony Van Dyck ... at Chatsworth* (1902); *A v Dyck, a Further Study* (1911); Max Rooses, *Chefs-d'oeuvres d'Antoine van Dyck* (Antwerp, 1901), *Antoine Van Dyck* (Paris, 1902), Frank Newbolt, *Etchings of Van Dyck* (1906), É Schaeffer, *Van Dyck* (Stuttgart and Leipzig, 1909, one of the series of Klassiker der Kunst). (H HY, X)

VAN DYKE, HENRY (1852–1933), American writer, was born in Germantown (Pa.), Nov. 10, 1852. He studied at the Brooklyn Polytechnic Institute, Princeton university (M.A., 1876), the Princeton Theological School, and the university of Berlin In 1879 he entered the Presbyterian ministry, becoming pastor at Newport, Rhode Island; in 1883 he became pastor of the Brick Presbyterian Church, New York City. In this capacity his preaching gave him a national reputation

In 1900 he became professor of English literature at Princeton. During 1902–3 he served as moderator of the Presbyterian Church in the United States. In 1908–9 he was American lecturer at the Sorbonne In 1913 President Wilson appointed him minister to Holland and Luxembourg, but he resigned in 1917.

Among his best works are his "outdoor essays," especially *Little Rivers* (1895) and *Fisherman's Luck* (1899). His short stories, notably *The Other Wise Man* (1896) and the collections *The Ruling Passion* (1901) and *The Blue Flower* (1902), were extremely popular. His other publications include *The Reality of Religion* (1884), *Days Off* (1907), *Out-of-Doors in the Holy Land* (1908); *Collected Poems* (1911); *Fighting for Peace* (1917); *The Valley of Vision* (1919); *Companionable Books* (1922), and (with Tertius Van Dyke) *Light My Candle* (1926), *The Man Behind the Book* (1929).

VANE, SIR HENRY (1589–1654), English secretary of state, born at Hadlow, Kent, on Feb. 18, 1589, was educated at Brasenose College, Oxford, entered Gray's Inn in 1606, and was knighted in 1611 He purchased various court offices, and sat in parliament for various constituencies from 1614 onwards. Vane was sent on many foreign missions, and in 1630 became one of the king's chief advisers. He was made a commissioner of the Admiralty in 1632 and for the colonies in 1636. He was one of the eight privy councillors appointed to manage affairs in Scotland on the outbreak of the troubles there, and on Feb. 3, 1640, through the influence of the queen and of the marquis of Hamilton and in opposition to the wishes of Strafford, he was made secretary of state in the room of Sir John Coke.

In the Short Parliament, which assembled in April, it fell to Vane to demand supplies He proposed that the king should give up ship-money and receive in return twelve subsidies. Parliament proved intractable and was dissolved on May 5 to prevent a vote against the continuance of the war with the Scots In the impeachment of Strafford, Vane asserted that Strafford had advised the king at a meeting of the privy council to employ the Irish army against England. He was on bad terms with Strafford, who had opposed his appointment to office Vane was accused of collusion and treachery, and there is no doubt that he desired Strafford's removal, believing that his sacrifice would satisfy the demands of the parliament. Nevertheless, the charge that he deliberately compassed his destruction is not proved Suspicions of his fidelity, however, increased, and after accompanying the king to Scotland in August 1641, he was dismissed from all his appointments on Nov. 4, on Charles's return.

Vane immediately joined the parliament; he was placed on the committee for Irish affairs on Dec. 13, was made lord lieutenant of Durham on Feb. 10, 1642, became a member of the committee of both kingdoms on Feb. 7, 1644, and in this capacity attended the Scots army in 1645, while the parliament in the treaty of Uxbridge demanded for him from Charles a barony and the repayment of his losses. He adhered to the parliament after the king's death, and in the first parliament of the Protectorate he was returned for Kent, but the House had refused to appoint him a member of the council of state in February 1650. He died in 1654

VANE, SIR HENRY (1613–1662), English statesman and author, known as "the younger" to distinguish him from his father,

Sir Henry Vane (*q v*), was baptized on May 20, 1613, at Debden, Essex After an education at Westminster, and at Magdalen Hall, Oxford, he was attached successively to the embassies at Vienna, Leiden and Geneva He had already acquired strong Puritan views, and, in 1635, in order to obtain the free exercise of his religion, he emigrated to Massachusetts, where he was elected governor in 1636 After one year in office, he was defeated by Winthrop.

Vane returned to England in August 1637 He was made joint-treasurer of the navy with Sir W Russell in January 1639, was elected for Hull in the Short and Long parliaments, and was knighted on June 23, 1640 He at once became one of the leaders of the parliamentary party, and in 1643 he was the leading man among the commissioners sent to treat for a league with the Scots Vane, who was bitterly opposed to the tyranny of the Presbyterian system, succeeded in getting the proposed bond between the parties termed the Solemn League and Covenant, and further in substituting the whole expression "*according to the word of God and* the example of the best Reformed churches" for the latter part alone He succeeded to the leadership of the party on Pym's death and was engaged in all the principal negotiations which followed. His leadership ended when the Presbyterian party obtained the supremacy in parliament in 1646 During the subsequent struggle he was one of the six commissioners appointed to treat with the army by the parliament, and endeavoured to effect a compromise, but failed, being distrusted by both the Levellers and the Presbyterians His views of government may be studied in *The People's Case Stated*, written shortly before his death

In spite, however, of these free opinions, Vane still desired the maintenance of the monarchy and the constitution He supported the renewal of negotiations with the king and was appointed in 1648 one of the commissioners for the treaty of Newport He showed a desire to come to terms on the foundation of toleration and a "moderate episcopacy," of which Cromwell greatly disapproved, and opposed the shaking off of the conferences He remained in retirement until after the king's death On Feb 14, 1649 he was placed on the council of state, though he refused to take the oath approving the king's execution Vane served on innumerable committees of importance, and was assiduous in his attendance. He furnished the supplies for Cromwell's expedition to Scotland, and was one of the commissioners to negotiate a union between the two countries He was a leading member of the committee dealing with foreign affairs, and in 1651 went on a secret mission to negotiate with Cardinal de Retz To Vane, as chief commissioner of the navy, belongs largely the credit of the victories obtained against Van Tromp

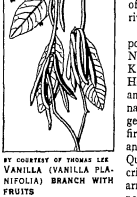
In domestic politics Vane continued to urge his views of toleration and his opposition to a state church. On Jan 9, 1650 he brought forward as chairman the report of a committee for the reform of the franchise on the property basis, the disfranchisement of certain existing boroughs, and increased representation to the large towns, the sitting members, however, were to retain their seats But Cromwell desired an entirely new parliament and the supremacy of the army representation On April 20 Cromwell forcibly dissolved the Long Parliament while in the act of passing Vane's bill. On the latter's protesting, "This is not honest; yea, it is against morality and common honesty," Cromwell fell a-railing at him, crying out with a loud voice, "O Sir Henry Vane, Sir Henry Vane; the Lord deliver me from Sir Henry Vane!" (Ludlow, *Mem* 1 353) Hitherto they had lived on intimate terms of friendship, but this incident created a permanent breach In his seclusion at Raby he now wrote the *Retired Man's Meditations* (1655) In 1656 he proposed in *A Healing Question* (reprinted in the "Somers Tracts," vol vi. ed Scott) a new form of government, insisting as before upon a Puritan parliament supreme over the army The seditious movements of the Anabaptists were attributed to his influence, and on July 29, 1656 he was summoned before the council Refusing to give security, he was a prisoner at Carisbrooke Castle from September to the end of the year. In the parliament of Richard Cromwell he was elected for Whitchurch, when he urged that the protector's power should be strictly limited

He allied himself with the officers in setting aside the protectorate and in restoring the Long Parliament, and on Richard Cromwell's abdication he became a member of the committee of safety and of the council of state appointed in May, was commissioner for the navy and for the appointment of army officers, managed foreign affairs and superintended finance He adhered to Lambert, remained a member of the government after the latter had turned out the Long Parliament, and endeavoured to maintain it by reconciling the disputing generals and by negotiating with the navy, which first deserted the cause In consequence, at the restoration of the Long Parliament he was expelled from the House and ordered to retire to Raby.

At the Restoration, Vane was imprisoned in the Tower by the king's order After several conferences between the houses of parliament, it was agreed that he should be excepted from the indemnity bill, but that a petition should be sent to Charles asking that his life might be spared The petition was granted But the new parliament of 1661 demanded his trial on the capital charge, and Vane was taken back to the Tower in April 1662 from the Scilly Isles, where he had been imprisoned On June 2 he appeared before the king's bench to answer the charge of high treason, when he made a bold and skilful defence, asserting the sovereign power of parliament in justification of his conduct. He was found guilty, and executed on June 14, 1662

BIBLIOGRAPHY.—Article by C. H Firth in *Dict. of Nat Biog*; S R Gardiner's *Hist of England*, his *Great Civil War* and his *Commonwealth*, and Clarendon's *Hist of the Rebellion*, and the contemporary memoirs and diaries; Hist MSS. Comm MSS. of duke of Buccleuch, n. pt ii 736, Masson's *Life of Milton*, iv 442 and *passim*; the sonnet addressed by Milton to Vane, and W. W. Ireland, *Life of Sir Henry Vane the Younger* (1905).

VAN GOGH: *see* GOGH, VINCENT VAN



VAN HORNE, SIR WILLIAM CORNELIUS (1843–1915), Canadian financier, was born in Will county, Ill., U.S.A., Feb 3, 1843, of Dutch descent. He was educated in the common schools of the state, and in 1857 began work as office boy in a railway station. In 1881 he was appointed general manager of the Canadian Pacific railway For the successful completion of this great road his strong will and mental grasp were largely responsible, and he controlled and extended its operations. In 1884 he became vice-president of the line, in 1888 president, and in 1899 chairman of the board of directors. After the Spanish-American War (1898) he became one of the chief promoters of railway and industrial enterprises in Cuba. He died at Montreal on Sept. 11, 1915.

VANILLA, a flavouring agent largely used in the manufacture of chocolate, in confectionery and in perfumery. It consists of the fermented and dried pods of several species of orchids belonging to the genus *Vanilla* The name of the genus comes from the Spanish *Vamilla*, a diminutive of *vaina*, a pod. The great bulk of the commercial article is the produce of *V. planifolia*, a native of southeastern Mexico, but now largely cultivated in several tropical countries, especially in Bourbon, the Seychelles, Tahiti and Java The plant has a long fleshy stem and attaches itself by its aerial rootlets to trees; the roots also penetrate the soil The leaves are alternate, oval-lanceolate and fleshy; the light greenish flowers form axillary spikes. The fruit is a pod from 6 to 10 in. long, when mature, about half-an inch in diameter The wild plant yields a smaller and less aromatic fruit, distinguished in Mexico as *Baymilla cimarona*, the cultivated vanilla being known as *B. corriente*

Mexican vanilla is principally consumed in the United States. In Bourbon large areas are under cultivation; the crop is sent to Bordeaux, the chief centre of the trade in France. Its odour is said to differ from the Mexican variety in having a suggestion of tonka bean. The best varieties of vanilla pods are of a very dark chocolate brown or nearly black colour, and are covered with a crystalline efflorescence technically known as *givre*, the presence of which is taken as a criterion of quality. The peculiar fragrance of vanilla is due to vanillin, $C_8H_8O_3$, which forms this efflorescence Chemically speaking, it is the aldehyde of methyl-protocatechuic acid. It is not naturally present in the fleshy exterior of the pod, but is secreted by hair-like papillae lining its three internal angles, and ultimately becomes diffused through the viscid oily liquid surrounding the seeds. Besides vanillin, the pods con-

tain vanillic acid (which is odourless), about 11% of fixed oil, 2·3% of soft resin, sugar, gum and oxalate of lime.

Vanillin forms crystalline needles, melting at 81° C. and soluble in alcohol, ether and oils, hardly soluble in cold, but more so in boiling water. Vanillin has been found in Siam benzoin and in raw sugar, and has been prepared artificially from coniferin, a glucoside found in the sapwood of fir-trees, from asafoetida, and from a constituent of oil of cloves named eugenol. It is now prepared synthetically on a commercial scale in Germany.

BY COURTESY OF THOMAS LEE VANILLA (VANILLA PLANIFOLIA) BRANCH WITH FRUITS

VANINI, LUCILIO, or, as he styled himself in his works, GIULIO CESARE (1585–1619), Italian free-thinker, was born at Taurisano, near Naples. He studied at Rome, Naples, and at Padua, and was ordained priest. Subsequently he led a roving life in France, Switzerland and the Low Countries.

Vanini was obliged to flee from Lyons to England in 1614, but was imprisoned in London for some reason for 49 days. Returning to Italy he made an attempt to teach in Genoa, but was driven once more to France, where he tried to clear himself of suspicion by publishing a book against atheists, *Amphitheatrum aeternae providentiae divino-magicum* (1615). Though the definitions of God are somewhat pantheistic, the book is sufficiently orthodox, but the arguments are largely ironical, and cannot be taken as expounding his real views. Vanini expressly tells us so in his second (and only other published) work, *De admirandis naturae reginae deaeque mortalium arcanis* (Paris, 1616), which, originally certified by two doctors of the Sorbonne, was afterwards re-examined and condemned. Vanini then left Paris, where he had been staying as chaplain to the maréchal de Bassompierre, and began to teach in Toulouse. In Nov. 1618 he was arrested, and after a prolonged trial was condemned as an atheist. He was burnt on Feb. 9, 1619.

VANLOO, CHARLES ANDREW (1705–1765), subject painter, a younger brother of John Baptist Vanloo (1684–1745), a well known portrait painter, was born at Nice on Feb 15, 1705. He received some instruction from his brother, and like him studied in Rome under Luti. In 1734 he settled in Paris, and in 1735 became a member of the French academy; he was decorated with the order of St. Michael and appointed principal painter to the king. He died in Paris on July 15, 1765.

VANNES, a town of western France, capital of the department of Morbihan, 84 mi. N.W. of Nantes on the railway to Brest. Pop. (1936) 22,352. Vannes (*Dariorigum*), the capital of the Veneti (whence *Gwenea*, the Breton name of the town), led the Armorican league against Julius Caesar, who in 56 B.C. overcame their fleet and opened up their country by six roads. St. Paternus, the first bishop, was consecrated in 465. In the 5th century Vannes was ruled for a time by independent counts, but soon came under the yoke of the Franks. Nomenoé, the lieutenant of Louis I, the Pious, in Brittany, assumed the title of king in 843, and one of his brothers was the founder of a line of counts who resisted the Normans in the 9th and 10th centuries. Vannes became part of the duchy of Brittany at the end of the 10th century. The estates of Brittany met there for the first time in 1203. In the course of the War of Succession the town was besieged in 1342. Duke John IV built here the castle of L'Hermine and made it his habitual residence. In 1487 the town was for a year in the hands of Charles VIII of France. In 1532 Brittany was definitively united to France.

Vannes is 10 mi. from the open sea, at the confluence of two streams forming the Vannes river, which opens into the landlocked gulf of Morbihan about a mile below the town. The old town, lying on a hill facing the south, is surrounded by fortifications of the 14th, 15th and 17th centuries, pierced by four gates and flanked by nine towers and five bastions, connected by battlements. In the Constable's tower Olivier de Clisson was confined in 1387. The modern suburbs, with the port and public buildings, surround the old town. The archaeological museum includes one of the richest collections of prehistoric remains in Europe. The cathedral of St Peter, burned by the Normans in the 10th century, was rebuilt in the 13th, 15th and 18th centuries. It has remains of a cloister. The curious round Chapelle du Pardon to the left of the nave was built in 1537 in the Italian style. Among the industries are tanning and cotton weaving. The port of Vannes, to the south of the town, is formed by the Vannes river and is accessible only to small vessels.

VAN RENSSELAER, STEPHEN (1764–1839), U.S. political leader and soldier, "last of the patroons," was born at New York city, Nov. 1, 1764. He was fifth in descent from Killian Van Rensselaer, original patroon of Rensselaerwyk, N.Y. He was a member of the New York assembly 1789–90, 1808–10, and in 1818, a member of the state senate 1791–95 and of the national house of representatives 1822–29. He served as a major-general in the second war with Great Britain, commanding the first division of the detached militia of the state of New York, and on the 13th of October 1812 was defeated at the battle of Queenston Heights. Because he was a Federalist he was severely criticised and censured for this defeat and resigned from the army. At the close of the war the Erie Canal project was renewed, and from 1816 till his death he was a member of the board of canal commissioners, and for nearly 15 years was its president. In 1818 he was again elected to the assembly; in 1819 he became a regent of the state university of which he was for a time chancellor. From 1822 to 1829 he was a member of the national house of representatives, and there voted for John Quincy Adams for the presidency. He died at Albany (N.Y.), Jan. 26, 1839.

VANSITTART, HENRY (1732–1770 or 1771), Anglo-Indian governor, was born in London on June 3, 1732, and educated at Reading school and Winchester college. He joined the society of the Franciscans, or the "Hell-fire club" at Medmenham. In 1745 he entered the service of the East India company and sailed for Fort St. David. In 1760 he went to Bengal as president of the council and governor of Fort William; deposing the subadar of Bengal, Mir Jafar, he replaced him by his son-in-law, Mir Kasim. In 1762 he made a treaty with Mir Kasim, checking the system of private trading by the company's servants. The repudiation by the council of this treaty led to war with the subadar, and Vansittart resigned and returned to England in 1764. In 1769 he was made a director of the company, and left England for India, but his ship was lost at sea in 1770 or 1771.

VAN'T HOFF, JACOBUS HENRICUS (1852–1911), Dutch physical chemist, was born in Rotterdam on Aug. 30, 1852. He studied at the Polytechnic at Delft, at the University of Leyden, then under Kekulé at Bonn, Wurtz at Paris in the École de Medecine and, finally, with Mulder at Utrecht, where he obtained his doctorate in 1874. In 1876 he became lecturer in physics at the veterinary school, Utrecht. In 1878 he was appointed professor of chemistry, mineralogy and geology in Amsterdam university. In 1896 he went to Berlin as professor to the Prussian academy of sciences, largely because this post involved no burden of administrative duties. He accepted an honorary professorship in the university so that he might lecture if he wished. He was elected a foreign member of the Royal society in 1897 and awarded its Davy medal in 1893. He was the first recipient of the Nobel prize for chemistry (1901). This was awarded for "his services in connection with the discovery of the laws of chemical dynamics and osmotic pressure in solutions." He died on March 1, 1911, at Steglitz, Berlin.

Van't Hoff's first research (his doctorate thesis) was on cyanacetic and malonic acids but his earliest important contribution to science was made in 1874. Starting with the results of the work of Wislicenus (*q.v.*) on the lactic acids, van't Hoff showed that the four valencies of the carbon atom were probably directed in space towards the four corners of a regular tetrahedron. In this way optical activity, shown to be always associated with an "asymmetric carbon atom," could readily be explained. An identical idea was put forward two months later (Nov. 1874), quite

independently, by J. A. Le Bel (*q.v.*), whose name is generally linked with that of van't Hoff in connection with the theory of asymmetric carbon. Though they had been fellow students under Wurtz, they "never exchanged a word about the carbon tetrahedron, though perhaps both of us cherished the idea in secret." The concept was attacked by Kolbe (*q.v.*), but its value was soon universally realized and it laid the foundation stone of the science of stereochemistry (*q.v.*). In 1877 van't Hoff published his *Ansichten über die organischen Chemie*. The book is almost unreadable but the second part contains the beginnings of his studies in chemical thermodynamics and affinity.

In 1884 was published van't Hoff's second important work. It dealt with the application of thermodynamics to chemical reactions, and was probably his greatest contribution to physical chemistry. He developed the principles of chemical kinetics, described a new method of determining the order of a reaction, and applied thermodynamics to chemical equilibria. In the course of this work he deduced the connection between the equilibrium constant of a reaction and the temperature, in the form of an equation known as the "van't Hoff isochor." He generalized this in the form of the "principle of mobile equilibrium," a special case of the principle developed by Le Chatelier (*q.v.*) at the same time (1884). In the course of the same study van't Hoff introduced the modern concept of chemical affinity as the maximum work obtainable as the result of a reaction and showed how it may be calculated from measurements of osmotic pressure, gas pressure and the e.m.f. of reversible galvanic cells. In 1886 he published the results of his study of dilute solutions and showed the analogy existing between them and gases, since both obey equations of the type $pv=RT$. During the next nine years he developed this work in connection with the theory of electrolytic dissociation enunciated by Arrhenius (*q.v.*) in 1887. The abnormality in the case of electrolytes was explained by the equation $pv=iRT$, in which the factor i was a measure of the deviation from the simple expression. As part of this work he carried out a series of researches on the conditions of formation and decomposition of double salts, and on his translation to Berlin in 1896, he developed this into the important phase rule study of the formation of oceanic salt deposits with special reference to those at Stassfurt, Saxony. With Wilhelm Ostwald (*q.v.*) he started the important *Zeitschrift für physikalische Chemie* in 1887, and the first volume contained the famous paper by Arrhenius on electrolytic dissociation, along with the fundamental paper of van't Hoff. Van't Hoff's publications include *La Chimie dans l'Espace* (1875); German edition 1876, and English 1898, *Etudes de dynamic chimique* (1884), revised and extended by E. Cohen as *Studien zur Chemischen Dynamik* (1896); *Vorlesungen über Bildung und Spaltung Doppelsalzen* (1897); and *Zur Bildung der Ozeanischen Salzablagerungen*, (i. 1905; ii. 1909).

See E. Cohen, *Jacobus Henricus van't Hoff, Sein Leben und Werken* (Leipzig, 1912); also Essay in Bugge's *Das Buch der Grossen Chemiker* (1930); J. Walker, van't Hoff Memorial Lecture in *Journal of the Chemical Society* (London, 1913); W. Ostwald, *Berichte der deutschen chemischen Gesellschaft* (1911); G. Bruni, *Annual Reports, Smithsonian Institute* (1914); B. Harrow, *Eminent Chemists of our Time* (1920); W. P. Jorissen and L. T. Reicher, *J. H. van't Hoff's Amsterdamer Periode* (1912).

VAN WERT, a city of western Ohio, U.S., the county seat of Van Wert county, on federal highways 30, 127 and 224; 34 mi. S.E. of Fort Wayne, Ind. It is served by the New York Central and Pennsylvania railways. Pop. (1930) 10,364. It is in an agricultural and dairying region, and has some manufacturing industries. Van Wert was settled about 1840, incorporated as a town in 1848 and as a city in 1903. Peony culture and making of Liederkranz cheese are important industries.

VAPEREAU, LOUIS GUSTAVE (1819–1906), French man of letters and lexicographer, was born at Orleans on April 4, 1819. After 1870 he was appointed prefect of Cantal (1870) and of Tarn et Garonne (1871–73). From 1877 to 1888 he was inspector-general of public instruction. He was the author of some excellent editions of the classics, and of works on political and social questions, but he is famous for his valuable *Dictionnaire universel des contemporains* (1858; 6th ed., 1893), brought up to date in 1895 by a supplementary volume. He also drew up a *Dictionnaire universel des littérateurs* (1876). He died in 1906.

VAPHIO, an ancient site in Laconia, Greece, on the right bank of the Eurotas, some 5 m. S. of Sparta, famous for its "bee-hive" tomb, excavated in 1889 by Dr. Tsountas. A walled approach, or δρόμος, about 97 ft. long, leads to a corbel-vaulted chamber 33 ft. in diameter, in the floor of which the grave was cut. The tomb, which probably belonged to Amyclae rather than to Pharis, as is commonly stated, is now almost entirely destroyed. Its contents (in the National Museum in Athens) are typical of the "First Late Minoan" period (about 1500 B.C.) and include engraved gems and amethyst beads, articles in gold, silver, bronze, lead, amber and crystal; also an iron ring, unusual at this early date. By far the finest objects are two golden cups with scenes in relief, picturing the capture of bulls.

See C. Tsountas, *Ἐφημερὶς Ἀρχαιολογική* (1889), 136–172; J. G. Frazer, *Pausanias's Description of Greece*, iii. 135 f. (with full bibliography); R. C. Bosanquet, *Journal of Hellenic Studies* (1904), xxiv. 317 ff., A. Riegl, *Jahreshefte d. osterr. arch. Institutes* (1906), ix. 1 ff.

VAPORIZATION, a general term denoting the change of state of any substance from solid or liquid to vapour. The converse change from vapour to liquid or solid is most often called condensation, though there are many other special terms employed in particular cases. The general phenomena of change of state as affected by heat have been described in the article HEAT. The most accurate methods of measuring the latent heat of vaporization or condensation are discussed in the article CALORIMETRY, and the application of the laws of thermodynamics to the subject is included in the article THERMODYNAMICS. Important practical applications of the properties of vapours will be found in other articles, such as LIQUEFACTION OF GASES; DISTILLATION; STEAM; STEAM ENGINE; TURBINE: STEAM. The chief object of the present article is to discuss the *physical* explanation of the phenomena, and to show how the various properties of vapours can be represented by equations, so that the effects to be expected under any conditions can be calculated.

Gases and Vapours.—In effect all gases may be regarded as vapours, since all may be liquefied and solidified under suitable conditions. Conversely we should expect that all vapours would behave as gases under conditions sufficiently far removed from those at which the corresponding liquid can exist. This is found to be the case for all stable vapours, which approximate more and more closely to the gas equation $pV=RT$ as the temperature is raised or the pressure reduced. In this equation V represents the volume occupied by unit mass at a temperature T on the absolute scale, and pressure P in any convenient units. The constant a is the factor required for reducing PV to heat units, and the value of the constant R in heat-units per degree is $1{\cdot}985/m$, where m is the molecular weight corresponding to the chemical formula for the molecule of the vapour considered. At any temperature below the boiling-point of the liquid, if the volume of the vapour is reduced, the deviations from Boyle's law will seldom exceed 1 per cent. But a sharp limit is set to the application of the gas equation by the *saturation-pressure* at which the vapour begins to condense. The pressure then remains constant, as the volume is further reduced at constant temperature, until the whole of the vapour is condensed. By experiments of this kind, Dalton established the law of saturation pressure, that for each vapour there is a unique relation between pressure and temperature defining the state in which alone the liquid and vapour can exist together in equilibrium.

Empirical Formulae for Saturation Pressure

$\log p = A + BT$	Dalton, 1800
$\log p = C \log (A - BT)$	Young, 1820
$\log p = AT/(B+CT)$	Roche, 1830
$\log p = A + Bt^1 + Ct^2$	Biot, 1844
$\log p = A + B \log t + C \log (T+c)$	Bertrand, 1887
$\log p = A - B/T - C(36t - t^3)/T$	Thiesen, 1900
$\log p = A - B/T - C \log t - DT + ET^2 + FT^3 + GT^4$	Goodenough, 1915

Biot's formula, though apparently the most ungainly and difficult to work, possesses some practical interest because it was adopted by Regnault (1847) for representing his observations on the saturation presses of steam, which were made with a mercury manometer 70 ft. high, and were much the most accurate

obtained for many years In spite of the five empirical constants in Biot's formula, Regnault found it necessary to use different formulae above and below 100° C. At that time the laws of thermodynamics had not been elucidated sufficiently to permit their application to the problem, but some theoretical basis might have been expected in the case of the later formulae

Theoretical Equation of Saturation Pressure.—The law according to which the saturation pressure of any vapour varied with the temperature was discovered by Carnot in 1824 by the direct application of his principle to the case of vaporization, and was first stated in the form.—"The increase of saturation pressure per degree is equal to the latent heat per unit increase of volume in vaporization multiplied by a function of the temperature (Carnot's function) which is the same for all substances" The law could not be applied until the form of this function had been determined Accordingly Carnot utilized the relation in the first instance for calculating values of his function from the very scanty and inaccurate data available for the latent heats of various substances But this failed to give any conclusive result owing to the poverty of the data (*See* THERMODYNAMICS) Clapeyron (1834) first stated the equation in the analytical form in which it is generally known as Clapeyron's equation,

$$L\ F't=(V-v)\ (dp/dt)_s \qquad (1)$$

in which L is the latent heat of vaporization corresponding to the increase of volume V−v from liquid to vapour, F't is Carnot's function of the temperature and $(dp/dt)_s$ denotes the increase of the saturation pressure per degree Ultimately, as the result of Joule's experiments on the mechanical equivalent of heat, denoted by J, and of Regnault's experiments on the gas-scale of temperature, denoted by T, it gradually became obvious (*see* HEAT) that Carnot's function must be very nearly equal to J/T. The absolute scale of temperature T was accordingly defined on Kelvin's suggestion by the condition T=J/F't, in which it is understood that the appropriate numerical value of J must be employed, depending on the units in terms of which heat and work are measured in the equation Putting a for 1/J, Clapeyron's equation may be written in the form,

$$L/ap(V-v)=(T/p)\ (dp/dT)_s \qquad (2)$$

The expression on the left is the ratio of the latent heat L to the equivalent $ap(V-v)$ of the external work of vaporization in heat units The expression on the right is the most convenient method of stating the rate of increase of saturation pressure with temperature, since it has the same numerical value, for a given substance under given conditions, in all systems of units. To find the expression for p in terms of T, we have merely to integrate equation (2) after substituting appropriate expressions for L and V in terms of p and T.

Rankine (1851) was the first to show that the total heat of an ideal vapour reckoned from the state of liquid at 0° C should be $H=L_0+St$, where S is the specific heat of the vapour at *constant* pressure, and L_0 the latent heat of vaporization at 0° C The total heat of the *liquid* reckened from 0° C is simply $h=st$, where s is specific heat of the liquid, and is taken as constant. Hence the latent heat L at any temperature t will be approximately,

$$L=H-h=L_0+(S-s)t. \qquad (3)$$

If the vapour also satisfies the gas law, as is generally the case at low pressures, we may substitute $ap\,V=RT$ in (2), and neglect v, which is generally less than a thousandth of V at atmospheric pressure. Equation (2) then reduces to the simple form, $L/RT^2=(dp/dt)/p$, which is easily integrated with the value of L from (3), and gives a theoretical equation for p,

$$\log_e p=A-B/T-C\log_e T \qquad (4)$$

where $B=L_0/R+(s-S)T_0/R$, $C=(s-S)/R$, and A is the constant of integration This equation must necessarily give a good first approximation to the saturation pressures if the values of the constants L_0, s, and S are correct Thus in the case of steam, if we take $L_0=594$ J, $s=0\cdot9967$ (the minimum specific heat of water) $S=0\cdot477=13R/3$, equation (4) gives values at low pressures which are correct to 0·1° C at a temperature as high as 60° C Beyond this point the approximation begins to fail, chiefly in the first instance because apV begins to deviate appreciably from the ideal value RT above assumed At 100° C the value of p given by (4) is already about 1·5% too small, corresponding to an defect of the same order of magnitude in the value of V This agreement verifies Clapeyron's equation (2), and the assumption $ap\,V=RT$ at low pressures, as well as equation (3) for L, but it is necessary to obtain consistent expressions for the defect of both L and V from these ideal values before equation (4) can be extended to higher pressures Rankine, who first gave a correct deduction of (4) (Trans. R.S.E 1865), came to the conclusion that both L and V must show an increasing defect from their ideal values as the pressure increased, but he was unable to trace the required connection between them Equation (4) is generally attributed to Dupré (1869), who deduced it by assuming a linear formula for the latent heat, and used it as a purely empirical formula by calculating the coefficients from observations at high pressures Bertrand, in his treatise on Thermodynamics, followed the same course, which is necessarily unsatisfactory, because it does not comply with the theoretical conditions, or give the true relations of the constants B and C to L and S.

Deviations of a Vapour from the Ideal State.—The manner in which a gas passes into a vapour and finally condenses, must be studied in the first instance by observing the gradual deviations from the gas law $apV=RT$, as the pressure is increased The simplest way of doing this is to find the departure from Boyle's law at various constant temperatures, which gives the whole story if the range of temperatures is sufficiently extended. Regnault (1847) was the first to make observations of this kind with sufficient accuracy in the case of CO_2. Rankine (1854) succeeded in representing these experimental results by a fairly simple equation in a convenient form,

$$P+A/V^2T=RT/aV. \qquad (5)$$

The second term, in which A is an empirical constant, represents the deviations from the gas law, and tends to vanish when V or T is large It is of the dimensions of a pressure, and may be interpreted as an internal pressure, varying as the square of the density, which is added to the external pressure P, and tends to reduce V below the ideal value According to Boyle's law, the product PV of the observed values of P and V at various pressures should be constant at each temperature at which observations are made, and should give a horizontal straight line when PV is plotted against P Equation (5) when plotted in this manner, gives a series of parabolas, each with its axis horizontal and its vertex at a height equal to half the initial value of PV This is easily seen by multiplying equation (5) by PV^2, which gives it in the form of a quadratic in (PV),

$$(PV)^2-(PV)(RT/a)+AP/T=0 \qquad (5)a$$

the two roots of which become equal when $P=RT/2aV$, and are imaginary at higher pressures The equation would evidently fall before this point was reached, but was found to be quite satisfactory for the restricted range of Regnault's experiments. It also represented his observations on the pressure-coefficient of CO_2 very closely, and Joule and Thomson found that it also satisfied their results for the cooling effect in expansion through a porous plug They found however that (5) was very inconvenient in form for their purpose, because it gave P as a quadratic function of 1/V, whereas they wanted V explicitly as a function of P They therefore transformed equation (5) by multiplying throughout by V/P, and making the approximation $PV=RT/a$ in the small term A/PVT, thus obtaining,

$$V=RT/aP-Aa/RT^2. \qquad (6)$$

The small term Aa/RT^2 is now of the dimensions of a volume, and may be interpreted as a first approximation to the reduction of volume A/PVT due to the internal pressure A/V^2T, as in equation (5) It also might be interpreted on the kinetic theory (which was expressly designed to explain the pressure of gases and vapours without assuming imaginary forces of attraction or repulsion between the molecules) as being due to a reduction in the

effective *number* of molecules per unit mass owing to the formation of multiple or complex molecules by coaggregation. This process is well known to occur in analogous chemical problems, where the proportions of different molecules existing in a gas mixture can be analysed and verified. On this view, the reduction of V below the ideal value RT/pP is due to a corresponding reduction in the number of *effective* molecules; and the formation of complex molecules is regarded as the first stage in the transition from the state of vapour to the state of liquid, in which nearly all the molecules are coaggregated. The reduction of volume $A_2/R^{1/2}$ given by the Joule-Thomson equation (6) is a function of the temperature only, and should be a very good first approximation to the coaggregation at low pressures according to the kinetic theory. If the isothermals are plotted on the PV—P diagram, they will all be straight lines, as is easily seen by multiplying (6), by P, so as to give the product PV. The slope of successive isothermals is proportional to $1/T^2$, and diminishes with rise of temperature. The diminution of slope with rise of temperature is to be expected on thermodynamic grounds, if the molecules combine with evolution of heat, which would afford the most natural explanation of the latent heat of condensation. The term A/PVT representing the reduction of volume according to Rankine's equation, though fitting exactly with the hypothesis of an internal pressure varying as the square of the density, might equally well represent the effect of coaggregation We might expect that the complex molecules would begin to combine *with each other* as the proportion of such molecules in the mixture increased with increase of density, and that the slope of each isothermal would increase accordingly, giving the parabolic form $(5)a$ in place of the rectilinear-isothermals given by (6). This is certainly true at high pressures near saturation, though the isothermals approximate more nearly to straight lines at temperatures above the critical point; but neither of these equations could be expected to apply to the liquid state, or even to the vapour in extreme cases, beyond the limits of the observations on which they were founded

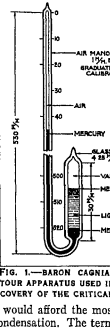


FIG. 1.—BARON CAGNIARD DE LA TOUR APPARATUS USED IN THE DISCOVERY OF THE CRITICAL POINT

The Continuity of State.—The theory of the continuity of state, which is now so familiar as an explanation of the relations between liquid and vapour, appears to have originated from the experiments of Andrews (*Phil. Trans.* 1869) on the properties of carbonic acid (CO_2) between the temperatures of 13° and 48° C, including the critical region. The vapour was confined in a capillary tube by a pellet of mercury, and the apparatus was arranged so that the volume could be varied by means of a screw plunger, while the tube was maintained at a steady temperature in a water bath. A similar capillary containing air subject to the same pressure was employed as a manometer (for details of apparatus *see* article MANOMETER). The isothermal curves obtained by plotting simultaneous values of P and V observed at the temperatures of 13.1°, 21.5°, 31.1°, 35.5° and 48.1° C., are shown in fig. 2B. They showed the well known discontinuities, required by Dalton's law, at the commencement and conclusion of condensation, but the sharp corners were rounded off at these high pressures, and the pressure did not remain quite constant during condensation, but showed a rise of about 2 per cent attributed by Andrews to an impurity of about 2 parts of air in 1,000 of CO_2. The dotted line shown in the figure has been added to Andrews' original diagram to indicate the saturation lines for the liquid and vapour, meeting at the critical point 31.1°, with the critical isothermal as a common tangent. At any point within the dotted boundary, *e.g.*, at 21.5°, the fluid exists partly in the state of vapour and partly in that of liquid, in stable equilibrium with the vapour, as is usually observed during the condensation of a vapour by compression at constant temperature. But Andrews showed very conclusively that a vapour could be transformed into a liquid by a continuous process without any breach of homogeneity, or separation into the two states of liquid and vapour, provided that the change was effected along any path on the diagram which did not intersect the dotted boundary curve. Thus if the vapour were taken at a temperature of 48°, and at a pressure of 80 atmospheres, and were then cooled *at constant pressure* to a temperature of 13°, at which it was certainly liquid, the fluid remained homogeneous throughout the process, and showed no sign of separation into two states at any point He concluded from these experiments that "the gaseous and liquid states are only widely separated forms of the same condition of matter, and may be made to pass into one another by a series of gradations so gentle that the passage shall nowhere present any interruption or breach of continuity"

James Thomson (*Proc. R.S.* 1871) extended this view to the region included by the boundary curve. He maintained that the discontinuities ordinarily shown at the beginning and end of condensation, were apparent rather than real. He quoted Donny's experiments as showing that, in the absence of dissolved air, the liquid curve AB in fig 2 A, could be traced along the extension BM to pressures far below the saturation line BCD, without any formation of vapour. It was possible to imagine the vapour curve ED similarly extended in the direction DN to pressures above saturation. This had been suggested by Kelvin (*Phil Mag.* 1870) on theoretical grounds, though it had not then been proved by experiment. The two curves thus extended might be joined into one continuous isothermal by the intermediate branch MCN. This branch would involve unstable conditions (V increasing with P) and could not be realized in practice, though it might be represented by some type of equation such as a cubic. If this could be done, it would have the great advantage of representing both liquid and vapour by a single equation of state, which would take account of all possible modes of transformation.

The Equation of van der Waals.—The continuous isothermal of James Thomson was first realized in the form of an equation by van der Waals in his famous essay *On the Continuity of the Liquid and Gaseous States* (Leyden, 1873), which put the whole theory in a more definite form. He assumed that the cohesion of the liquid, shown by Donny's experiments, could be attributed to an internal pressure, such as that invoked by Laplace to account for the surface tension He considered that this internal pressure should depend on the attraction of contiguous parts of the fluid for each other, and should vary as the square of the density, or as $1/V^2$. It would then also explain the deviations of the vapour from the ideal state, as in Rankine's equation for CO_2. Thus both liquid and vapour would be represented by the same equation, which implied that the molecules were identical, and that the two states differed only in density. The only modification necessary in Rankine's equation was the inclusion of the co-volume b in the last term, to represent the irreducible volume of the molecules themselves at high pressures, as demonstrated by Natterer (1854) This also had the effect of transforming the equation into a cubic in V as required by the theory of the James Thomson isothermal. We thus obtain the equation,

$$P+A/V^2=RT/a(V-b) \qquad (7)$$

The factor T in Rankine's expression for the internal pressure was omitted by van der Waals on the ground that an internal pressure, representing a force of attraction between the molecules, should be independent of the temperature. But this does not make any material difference to the critical relations. It will be evident that, for given values of P and T, equation (7) gives a cubic in V, and may have three real roots within certain limits representing the points of intersection, B,C,D, in fig. 1A, of the isothermal of T with the line of constant pressure P. The smallest of these roots, given by the point B, may be identified with the volume of the liquid, v, and the largest, given by the point D, with that of

the vapour, V, the middle root C corresponding to the unstable intermediate state imagined by James Thomson. The isothermal curve shown in the figure 1A, corresponds roughly with that given by equation (7) at 21.5°C, or T=294.6. As the temperature is raised towards the critical point at 31.1° C, the line BCD becomes rapidly shorter, and the three roots finally coalesce at the critical point, where the isothermal has a point of inflection with a horizontal tangent as shown in Andrews' diagram, fig 1B. The condition for three equal roots at this point gives the critical relations,

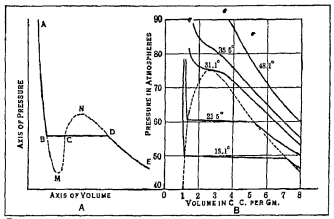

FIG. 2.—(A) JAMES THOMSON ISOTHERMAL, (B) ISOTHERMALS OF CO_2 (ANDREWS)

$$V=v=3b,\ P=A/27b^2,\ T=8A/27bR, \qquad (8)$$

as given by van der Waals, omitting the reduction factor a. These relations give the values of V, P and T, at the critical point in terms of the constants A, b and R, or *vice versa*. It will be seen that the results depend mainly on the value assigned to b, which is very small, and could not be determined satisfactorily from Regnault's observations at comparatively low pressures. The value of the constant A was taken from Regnault's observations, following Rankine's procedure, but that of b was selected to fit the critical temperature, T=304°, which was known with a fair degree of accuracy. The calculated values of the critical pressure and volume did not agree very well with Andrews' observations, but these were somewhat uncertain. The *qualitative* agreement was incredibly perfect in all essential respects with the James Thomson theory, and the equation of van der Waals was immediately accepted as the true and final solution of the problem.

Maxwell's Theorem.—The continuous isothermals represented by equation (7) could easily be plotted on the PV diagram as shown in fig 2, but an exact *quantitative* comparison was difficult, because van der Waals' theory, as originally presented, gave no indication of the manner in which the line BCD, representing the saturation pressure, should be drawn in relation to the continuous isothermal. This question was first solved by J. C. Maxwell (1875), who showed by a simple application of Carnot's principle, that the work of vaporization must be the same along either path, or that the line BCD at each temperature must cut off positive and negative loops of equal area from the continuous isothermal. The work of vaporization along BCD is simply $p(V-v)$; that along the curve is the integral of pdV from (7) between the same limits. The integration is easy, and gives the condition,

$$p(V-v)=(RT/a)\log_e(V-b)/(v-b)+A/V-A/v \qquad (9)$$

Fig. 3 shows the saturation lines correctly drawn in accordance with Maxwell's rule in relation to the isothermal curves given by (7) for the temperatures 0°, 10°, 20° and 30° C. Below 0° down to −50° C, the saturation pressures given by (7) are marked on the saturation line aC_w for the liquid. The dotted curve AC shows the saturation line for the liquid and the saturation pressures as actually observed. Comparing the two curves, we see at once that the values of v calculated from (9) are all nearly 100% too large, and that the actual increase of saturation pressure between 10° and 30° C is nearly double that given by (7). This was not noticed at the time, because the saturation pressures were difficult to calculate from (9), and the volumes of the liquid were considered to be of little importance. Equation (7) gives a very simple expression for the internal latent heat L_i regarded as being equivalent to the work done against the internal pressure A/V^2 when the volume is increased from v to V at constant temperature. We find immediately, $L_i=A/v-A/V$ in work units. The work-equivalent of the latent heat L as ordinarily measured is obtained by adding to L_i the external work $p(V-v)$. L could also be calculated directly from Clapeyron's first relation (*see* article on THERMODYNAMICS, equation 29) by integrating $T(dp/dt)_v$ from v to V, along the continuous isothermal given by (7). We thus obtain, in work units, a quite different expression, namely, $L=(RT/a)\log_e(V-b)/(v-b)$; but it is easy to see that the two expressions for L are equal and exactly consistent with Maxwell's condition (9). These expressions show that any error in v will entail a corresponding error in L as calculated from (7), as is found to be the case on comparison with actual measurements of L which have since become available.

Clausius' Equations for Carbonic Acid and Steam.—To deduce the equation of saturation pressure from (9) in the form of a relation between p and T, as in (4), it would be necessary to eliminate V and v with the aid of (7), which is satisfied by both. This proved to be extremely difficult, as is shown by the case with transcendental equations. Clausius (*Phil Mag.* 1882) first succeeded in finding a practical solution in the form of a table of corresponding states, giving the values of p, V and v, as fractions of the critical pressure and volume, in terms of the temperature expressed as a fraction of the critical temperature. The table in this form could be applied to any equation of the type (7) provided that A were a function of the temperature only. If A were constant, as assumed by van der Waals, the saturation pressures given by the table could not be made to agree at all with observation. But by choosing a suitable expression for A as a function of the temperature, the saturation pressures could always be fitted as closely as desired, if the function were sufficiently complicated. In the case of CO_2, in order to make the saturation pressures as given by (7) agree with those observed by Andrews over the very limited range of his experiments, it sufficed to replace Rankine's T in the expression for the internal pressure, making it $A/\sqrt{T}$ as in (5). In order to make the equation represent the volumes of the liquid more closely, Clausius also found it necessary to replace V^2 in this term by $(V+b'')^2$, the empirical constant b'' being chosen to make the calculated value of v agree with observation at 20° C. The equation thus modified and

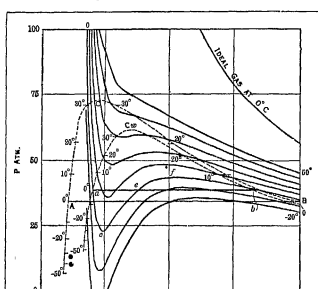

FIG. 3.—ISOTHERMALS GIVEN BY VAN DER WAAL'S EQUATION

developed normally takes the form shown in (10),

$$P+A/T(V+b'')^2=RT/a(V-b') \qquad (10)$$

which is still often quoted as applicable to CO_2, and gives fair agreement with observation from 0° to 30° C. But in spite of these additional complications, the equation would be of little use for practical purposes at low temperatures (where it is most

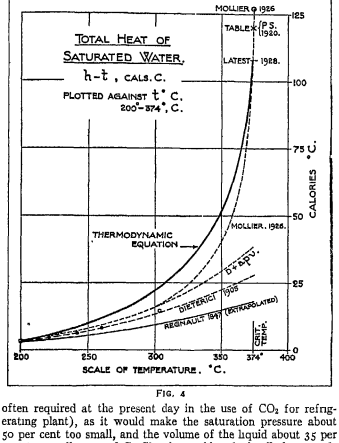

FIG. 4

often required at the present day in the use of CO_2 for refrigeratng plant), as it would make the saturation pressure about 50 per cent too small, and the volume of the liquid about 35 per cent too small at −50° C. Clausius could undoubtedly have made a much better approximation to the saturation pressures, if accurate observations of p had been available over a wider range, but the volumes of the liquid, and the values of the latent heat (which are most important for practical purposes) would still have been most unsatisfactory.

Owing to the restricted range of the observations available for CO_2, Clausius also applied his method to steam, for which Regnault's values of the saturation pressures were above suspicion, and extended over a much wider range. Having succeeded in representing the observed steam-pressures over the range 0° to 330° C by means of an equation similar to (10), but with a somewhat more complicated expression for A as a function of the temperature, Clausius was able to calculate the values of the critical temperature and pressure from the critical relations, which were very similar in form to (8). These gave the values, $t=332°$ C, and $p=134$ atmos., and should have afforded a good test of the theory, but no satisfactory observations were available for comparison. The old estimate, $t=362°$ C, made by de La Tour, for a solution of soda, might not apply to pure water, and the temperature was somewhat doubtful. The values given by Clausius brought the properties of steam more nearly into correspondence with those of CO_2, and the theory of the continuity of state was by that time so firmly established that everyone assumed that all the other properties of the fluid must fall naturally into line if the saturation pressures were correct. The value of the constant b'' was adjusted, as in the case of CO_2, to make the calculated value of v correct at 20° C, but the value given by the equation was nearly 100% too large at 300° C. This was regarded as unimportant, because engineers at that time were in the habit of neglecting the volume of the liquid, but the discrepancy would necessarily make a corresponding error in the calculated values of the latent heat according to van der Waals' theory. Some ten years later Cailletet and Colardeau succeeded in measuring the saturation pressures of steam up to the critical point, which they estimated as 365° C, confirming the old value given by de La Tour. They found the critical pressure at this point to be nearly 200 atmospheres, which greatly exceeded the value given by Clausius. Meanwhile more and more complicated equations on the lines of van der Waals' theory, were still being evolved by mathematicians, who were strongly attracted by the conception of an internal pressure applying equally to the gaseous and liquid states, but were not greatly concerned with the practical question of agreement with actuality. The qualitative agreement with the properties of the vapour were sufficiently striking to arrest attention, while the discrepancies with regard to the properties of the liquid and the latent heat entirely escaped notice owing to the extraordinary difficulties involved in the experimental measurement.

Thermodynamic Equation for the Liquid.—The failure of so many ingenious attempts to construct an equation of the van der Waals' type capable of representing the properties of the liquid satisfactorily, might be taken as strong presumptive evidence that his fundamental assumption of identity of molecular structure was unsound. The proved facts with regard to the continuous transition from vapour to liquid, or *vice versa*, at high pressures might just as well be explained on the hypothesis that the fluid consisted of a mixture of molecules of different types, the composition of the mixture being capable of continuous variation according to the conditions of temperature and pressure. If two phases or mixtures of different molecular composition were capable of coexistence in thermodynamic equilibrium under any given conditions, the fluid would tend to separate into two parts according to general laws, which were first comprehensively stated by J. Willard Gibbs (1875) in his papers on the equilibrium of heterogeneous substances. That a simple substance like water might possibly contain molecules of different types, was first suggested by Rowland as an explanation of the remarkable variation of the specific heat of water near the freezing point, which he attributed to the presence of a small proportion of *ice* molecules. The measurement of the specific heat of water up to 100° C by the continuous electric method (*see* CALORIMETRY) suggested that the variation at higher temperatures could be explained by supposing that water contained its own volume v of saturated steam, which would contribute the fraction $v/(V-v)$ of the latent heat of vaporization L to the total heat h of the water. This gave the very simple and convenient expression for h (*Phil. Trans.* 1902)

$$h=st+vL/(V-v)=st+av\mathrm{T}(dp/dt) \qquad (11)$$

which appeared to be capable of taking account of the variation of specific heat of the liquid at higher temperatures, and at the same time fitted perfectly with Clapeyron's equation, (2), and with all the properties of the liquid in relation to the vapour. Thus if we add L to both sides of (11) we obtain,

$$\mathrm{H}=st+\mathrm{VL}/(V-v)=st+a\mathrm{VT}(dp/dt) \qquad (12)$$

which gives the corresponding relation for the total heat H of the saturated vapour at the same temperature. Moreover it gives equally simple and exact expressions for the entropy of the liquid and vapour in equilibrium, namely,

$$\Phi=s\log_e(\mathrm{T}/\mathrm{T}_0)+vL/\mathrm{T}(V-v) \qquad (13)$$

$$\Phi=s'\log_e(\mathrm{T}/\mathrm{T}_0)+\mathrm{VL}/\mathrm{T}(V-v) \qquad (14)$$

From (11) and (12) we obtain a very useful relation between the volumes and total heats of the liquid and vapour at saturation,

$$v/\mathrm{V}=(h-st)/(\mathrm{H}-st) \qquad (15)$$

and from (11) and (13) we obtain a simple expression for the Gibbs' function, $\mathrm{G}=\mathrm{T}\phi_v-h$, which has the same value for water at saturation as for wet steam of any quality at the same temperature and pressure, namely,

$$\mathrm{G}=\mathrm{T}\phi_v-h=s\mathrm{T}\log_e(\mathrm{T}/\mathrm{T}_0)-st \qquad (16)$$

One of the chief advantages of (11) is that it completely solves the problem of finding the theoretical equation of saturation pressure so far as the liquid is concerned. As indicated above, Rankine had to neglect v entirely and to assume that s was constant. Whereas in (11) s denotes the constant minimum specific heat of the liquid, and the second term takes complete account of the variation of h in terms of the volume v. This term is exactly eliminated by adding the expression for L from Clapeyron's equation, leaving (12) as the equation to be integrated, from which the troublesome terms representing the volume of the liquid, and the variation of its specific heat, have both automatically disappeared. We have only to find consistent expressions for H and V, and the equation must be the exact differential of the corresponding equation of saturation pressure. The equation for the liquid was verified indirectly by the fact that this method gave correct values of the saturation pressures of steam up to 200° C, when the defect of H from Rankine's ideal value was determined by the differential throttling method. The corresponding values of V, as given by the Joule Thomson equation (6), were verified up to the same limit by the subsequent observations of Knoblauch (1905).

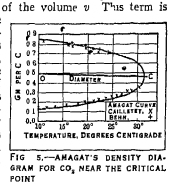

FIG 5.—AMAGAT'S DENSITY DIAGRAM FOR CO_2 NEAR THE CRITICAL POINT

Another method, which appears simpler at first sight, but requires equivalent integrations, is to find a consistent expression for the entropy Φ_x, from those for H and V, by integrating $(dH/T)-a(V/T)dP=dQ/T$. The value of $T\Phi_x-H$ for the vapour is then equated to the Gibbs' function (16) for the liquid. This necessarily gives the same result as integrating Clapeyron's equation in the form (12). It was also found that, if an equation of the van der Waals type, giving consistent values of H and V for the vapour, were combined with equation (11) for the liquid (instead of assuming *the same* equation for liquid and vapour), the combination would give much better results for L, and even for p itself, than Clausius' method. This afforded further presumptive evidence in favour of (11) as a suitable equation for the liquid.

Modified Joule-Thomson Equation.—The modification (6) of Rankine's equation which was adopted by Joule and Thomson to represent the deviations of gases from the ideal state, proved more convenient in practice than that of van der Waals, because it gave V directly in terms of P and T, instead of giving P as a cubic function of V, and also gave a much better account of the properties of CO_2 at moderate pressures. In applying the same equation to steam and other gases and vapours (*Proc. R.S.* June 1906, *Phil. Mag.* Jan. 1903) it was put in the more general form,

$$V-\frac{b}{\eta}=RT/aP-c \qquad (17)$$

in which b is the covolume as in van der Waals's equation, and c represents the reduction of volume due to coaggregation or pairing of molecules. To a first approximation, c is a function of the temperature only, as in the original Joule-Thomson equation (6), but it may vary with temperature in different ways for molecules of different types. Thus in the case of steam, in order to satisfy the adiabatic equation, $P/T^{10/3}=$constant, cP/T must be constant along any adiabatic, in which case c must vary as $1/T^{10/3}$. The value of c was determined by the throttling method on this assumption, and found to be 26·3 c.c/gm. at 100° C. The equation in this simple form gave very convenient expressions for the total heat H, and the entropy Φ of the dry vapour. (*See* THERMODYNAMICS.) When taken in conjunction with equation (16) for the liquid, it appeared that the effect of coaggregation on the saturation pressures could be represented by simply adding the term $a(c-b)p/RT$ to Rankine's theoretical equation (4) for an ideal vapour, which was about 1·5% in error at 100° C without this addition, though agreeing closely with observation at low pressures. The addition of the term required by (18) to represent the coaggregation, brought the values of p into good agreement with Regnault's observations up to 200° C. Beyond this point the values of p given by the modified equation (4) began to deviate gradually from observation, until they were about 15% too small at 365° C according to the observations of Cailletet and Colardeau. It was evident that the first approximation, represented by c, though very good at moderate pressures, or at high superheats, would necessarily fail at high pressures near saturation, because it took no account of the higher degrees of coaggregation due to the combination of the complex molecules with each other. This effect could most easily be represented by employing, in place of c for the coaggregation, a series of the form,

$$c(1+Z+Z^2+Z^3+\text{ etc. }\dots)=c/(1-Z) \qquad (18)$$

representing a geometrical progression with first term c and common ratio Z, where $Z=kcP/T$, being proportional to the mass of the coaggregated molecules present in the vapour. It was found however that, in order to represent the values of p satisfactorily at pressures up to 200 lb., the second term Z in this series must be absent, and that the common ratio should be Z^2 instead of Z, giving the sum of the series in the form $c/(1-Z^2)$. This was confirmed by the observations on the values of V up to the critical point described in the preceding section. Unfortunately the value

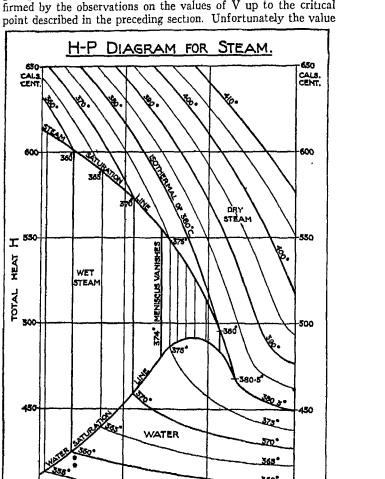

FIG. 6

of Z thus found would not necessarily give correct values of H, unless the adiabatic equation, which required an expression of this type for the coaggregation, remained true up to the critical point. No values of H were at that time available beyond 200° C, and the series suggested by the observations of V was quite inconsistent with the orthodox theory of the critical state, which could not be questioned without the most conclusive experimental evidence. The only practicable method of verifying the adiabatic at such high pressures would be to measure the values of H and h, in addition to those of V and v, which would be a very laborious

and expensive undertaking.

The probability of this solution was first suggested by measurements of the saturation volumes of water and steam in sealed tubes of quartz-glass, which showed that the meniscus vanished at 374° C, and that the densities did *not* become equal at this point, as commonly assumed, but were 0·438 gm /c c for the liquid and 0·264 gm /c c. for the vapour. Moreover, the difference of density could be traced nearly up to 380° C, with suitable illumination, under favourable conditions, and the coefficients of expansion remained finite. These phenomena could not be reconciled with van der Waals's theory, but could be represented satisfactorily by the modified equation (17) with the series $c/(1-Z^2)$ in place of c. Many other stable liquids showed similar effects when carefully purified, but the equilibrium under these critical conditions might be completely upset by small traces of air or other impurities. In order to complete the proof, it was necessary to measure the total heats of both water and steam in the critical region. This had not previously been attempted, owing to grave experimental difficulties, but was successfully accomplished by the jacketed condenser method as described in the article CALORIMETRY.

H-P Diagram for Steam.—The application of the method described above proved to be less troublesome than in the case of water, because no air cushion was required to protect the gauge from vibration, since the steam itself acted as a perfect cushion, and the gauge readings were always steady. It was most important however to keep a continuous check on the purity of the water, and especially on the absence of air, which appeared to have a profound effect on the attainment of true equilibrium between the complex molecules at high pressures near the critical point. The apparatus required for *eliminating air* was very simple and effective. The water for supplying the pump was passed through two boilers in series, which were kept boiling with a free escape of steam. Before reaching the first boiler the water was heated nearly to the boiling point by passing through a regenerator. Most of the air was carried off with the steam from the first boiler, the remainder, to a very small fraction, was eliminated by the second. The air-free water then returned through the regenerator, and was further cooled to atmospheric temperature before being delivered to the pump. With ordinary distilled water, which may contain from a tenth to a twentieth of its volume of air at atmospheric pressure (about 1 part in 10,000 by weight) an almost continuous stream of bubbles could be observed issuing with the condensate through the glass inspection tube attached to the outlet of the condenser. It was impossible under these conditions to obtain consistent values of H owing to accidental fluctuations in the air content of the water. With the air-free apparatus in action, not a single bubble could be seen in the course of an hour's run, and the observations near saturation became incredibly more consistent. The elimination of air appeared to be just as important as in the case of the observations on the saturation volumes in the quartz tubes by the static method. It was also important to keep the fluid in the superheater at a steady temperature for a sufficient time to permit the attainment of true equilibrium before passing into the high-pressure pocket where its initial temperature and pressure were measured. It was then throttled to atmospheric pressure before entering the condenser, where its *total heat* was measured by observing the rise of temperature of a steady stream of cooling water, and deducing the increase of total heat as explained in the article CALORIMETRY.

The results thus obtained on the basis of the above are exhibited in the annexed figure 3, in which the observed values of the total heats are plotted against the pressure, and the temperatures are indicated by isothermal lines. The observations of H and h confirmed those of the saturation volumes by showing that the *saturation lines* for water and steam could be traced beyond 374° C and appeared to meet in a sharp cusp tangential to the isothermal of 380·5° C, which made an abrupt bend at this point, and became parallel to the lower isothermals of water, showing that all the active molecules of steam were condensed. Taking $V-b$ from the modified equation (17), the observed values of H for dry steam were found to agree with the fundamental relation,

$$H-B=(13/3)aP(V-b)+abP, \qquad (19)$$

as required by the equation for the adiabatic. (*See* THERMODYNAMICS.) The observations of h for the liquid verified equation (11), which explains the peculiar form of the water saturation line, since it requires that the active molecules of steam in the liquid must be condensed with increase of pressure at the same rate per unit volume as in the vapour.

A further verification of the system of equations (11), (17), and (19), was afforded by calculating the values of the saturation pressure from the theoretical equation given by (11) and (17) as above explained. These agreed with the pressures previously observed by Holborn and Baumann (1910) to within 0·3° C on the average over the whole range from 0° to 374° C. But the equation went further and continued to give values of p agreeing with observation up to 380·5° C, where it came to a stop, and refused to give any solution at higher temperatures, thus verifying the limit observed by direct experiment. (*Proc. Roy. Soc.* Sept. 1928.)

The theory of the continuity of state, though very fascinating, was most artificial, and was founded on a somewhat inadequate experimental basis. It has now served its turn, and may have to give place to an experimental study of the molecular structure of liquids as affording a more natural explanation of the phenomena of change of state. (H. L. C.)

VAR, a department of France, formed in 1790 of a part of Lower Provence, but in 1860 reduced by the transfer of the district of Grasse to the newly formed department of the Alpes-Maritimes, which is the reason why the Var does not now flow in the department to which it gives its name. It is bounded north by the department of the Basses-Alpes (the Verdon river forming the boundary), east by that of the Alpes-Maritimes (the Siagne stream forming the limit), south by the Mediterranean, and west by the department of the Bouches-du-Rhône. Pop. (1936) 398,662. Area 2,326 sq mi.

The east of the department is built up of the Estérel and the Massif des Maures, a block of Archaean and Palaeozoic rocks, the two parts named being separated by the Argens river; this massif reaches a height of 2,500 feet. The rest of the department is mostly made up of the east-to-west lines of the Alpes de Provence which include the chain of Sainte Beaume (3,786 ft.) in the west, but rise to 5,620 ft. at the Signal des Chens in the northeast. The valley lines for the most part run east and west between the hills, but the Gapeau river makes its way to the coast southwards between the outliers of Sainte Beaume and the Massif des Maures, and other streams have north-to-south sections cutting through lines of hills. The coast shows evidences everywhere of a recent sinking movement and has numerous islands, notably the Iles d'Hyères, Porquerolles, Ile de Riou, etc. The harbour of Toulon is a famous case of a sunken valley. The climate is mild on the coast, St. Raphael and Hyères being much frequented winter resorts. The department now forms the bishopric of Fréjus (4th century) which is in the ecclesiastical province of Aix-en-Provence.

The chief industries are spinning and weaving of silk, manufacture of soap, paper, cork, pottery and tanning. Tobacco is grown and there is much fishing for tunny and anchovy. Trade is in wood and coal. Cut flowers are largely exported from Hyères. The department forms the bishopric of Fréjus (4th century), under Aix-en-Provence. It is in the *académie* (educational division) of Aix, where is its court of appeal, and is in the region of the XV army corp. There are two arrondissements (Draguignan and Toulon), 30 cantons and 151 communes. The principal towns are Toulon, La Seyne, Hyères, Draguignan, its political capital, Brignoles and Fréjus.

VARALLO SESIA, a town of Piedmont, Italy, in the province of Novara, from which it is 34 mi. N.N.W. by rail, situated in the valley of the Sesia, 1,480 ft. above sea-level. Pop. (1936) 3,642 (town); 8,540 (commune). The churches of S. Gaudenzio S. Maria delle Grazie and S. Maria di Loreto, all contain works by Gaudenzio Ferrari (1471–1546), who was born in the neighbouring Valduggia, while the Sacro Monte, a place of pilgrimage rising above the town (1,995 ft.), is approached by a path leading past 45 chapels.

VARAŽDIN, a town of Croatia, Yugoslavia. Pop (1931) 14,609. Varaždin possesses an old castle, a cathedral, several churches, monasteries and schools, and a university There are woollen mills, and trade in timber, wine, pigs, fruit, tobacco, spirits, stoneware and silk. Coal is mined in the Varaždin Mts The celebrated sulphur baths of Constantins-Bad or Toplitz, known to the Romans as Thermae Constantianae, are about 10 mi. S. Varaždin was occupied by Italian troops in World War II.

VARDANES, the name of two Parthian kings

VARDANES I succeeded Artabanus II, probably his father, in A.D. 40 (Joseph. *Ant.* xx. 3, 4), but had continually to fight against his rival Gotarzes (*q.v.*). The coins show that he was in full possession of the throne from 42 to 45. In 43 he forced Seleucia on the Tigris to submit to the Parthians again after a rebellion of seven years (Tac. *Ann* xi. 9). Ctesphon, the residence of the kings on the left bank of the Tigris, opposite to Seleucia, naturally profited by this war; and Vardanes is therefore called founder of Ctesiphon by Ammianus Marc xxiii. 6, 23 He also prepared for a war against Rome, with the aim of reconquering Armenia (*cf.* Joseph, *Ant* xx 3, 4), but did not dare to face the Roman legions (Tac. *Ann.* xi. 10). In a new war with Gotarzes he gained a great success against the eastern nomads In the summer of 45 he was assassinated while hunting, and Gotarzes became king again.

VARDANES II. rebelled against his father Vologaeses I. in A D 54 (Tac. *Ann.* xiii. 7). We know nothing more about him and it is not certain whether the coins of a young beardless king, which are generally attributed to him, really belong to him (Wroth, *Catalogue of the Coins of Parthia*, p L. ff.).

VARENIUS, BERNHARDUS (BERNHARD VAREN) (1622–1650), German geographer, was born at Hitzacker on the Elbe, in the Luneburg district of Hanover. Varenius studied medicine at Königsberg and Leyden universities intending to practise at Amsterdam. But the recent discoveries of Tasman, Schouten and other Dutch navigators, and his friendship for Blaeu and other geographers, attracted Varenius to geography. He died in 1650

In 1649 he published, through L. Elzevir of Amsterdam, his *Descriptio Regni Japoniae* which included a Latin translation of part of Jodocus Schouten's account of Siam (*Appendix de religione Siamensium, ex Descriptione Belgica Jodoci Schoutenii*), and chapters on the religions of various peoples In 1650 appeared, also through Elzevir, his best-known work, *Geographia Generalis*, in which he endeavoured to lay down the general principles of the subject on a wide scientific basis. The work is divided into—(1) absolute geography, (2) relative geography and (3) comparative geography. The first investigates mathematical facts relating to the earth as a whole, its figure, dimensions, motions, their measurement, etc. The second part considers the earth as affected by the sun and stars, climates, seasons, the difference of apparent time at different places, variations in the length of the day, etc The third part treats briefly of the actual divisions of the surface of the earth, their relative positions, globe and map-construction, longitude, navigation, etc.

Varenius, with the materials at his command, dealt with the subject in a truly philosophic spirit; and his work long held its position as the best treatise in existence on scientific and comparative geography The work went through many editions. Sir Isaac Newton introduced several important improvements into the Cambridge edition of 1672; in 1715 Dr. Jurin issued another Cambridge edition with a valuable appendix; in 1733 the whole work was translated into English by Dugdale, and in 1736 Dugdale's second edition was revised by Shaw. In 1716 an Italian edition appeared at Naples; in 1750 a Dutch translation followed; and in 1755 a French version, from Shaw's edition, came out at Paris.

See Breusing, "Lebensnachrichten von Bernhard Varenius" (*Geogr Mittheil.*, 1880); H Blink's paper on Varenius in *Tijdschr van het Nederl. Aardrijkskundig Genootschap* (1887), ser. ii pts. 3; and F. Ratzel's article "Bernhard Varenius," in *Allgemeine Deutsche Biographie*, vol. xxix. (Leipzig, 1895).

VARESE, a town and provincial capital of Lombardy, Italy, 18 m. by rail W. of Como, and 37 m. N.W. of Milan, 1,253 ft. above sea-level. Pop. (1936) 23,348 (town); 44,832 (commune). It is a favourite summer and autumn resort of the Milanese. The church of S. Victor has an ancient baptistery (dating from the 9th century but rebuilt in the 13th) The fine campanile of the church is 246 ft high. To the northwest is the pilgrimage church of the Madonna del Monte (2,885 ft).

VARGAS, GETULIO DORNELLAS (1883–), president of Brazil, born April 19, 1883, at São Borja, Rio Grande do Sûl. was graduated with a degree in law and social sciences from the University of Pôrto Alegre in 1907. After serving in the legislature of Rio Grande do Sul, he became president of the state, 1928–30. Vargas was president of Brazil, 1930–45, and in 1946 was elected to the national senate Elected in Oct. 1950, he again became president of Brazil in Jan 1951.

VARIA (mod Vicovaro), an ancient village of Latium, Italy, in the valley of the Anio, on its right bank, and on the Via Valeria, 8 mi. N E of Tibur (Tivoli) It was probably an independent town and not within the territory of Tibur, and Horace speaks of it as Sabine. Some remains of its walls, in rectangular blocks of travertine, still exist; and there is a chapel of S. Giacomo with beautiful carvings by Domenico Capodistria (d 1464 there) and Giovanni Dalmata. One mile to the east is a picturesque gorge of the Anio, in which may be seen remains of the ancient aqueducts which supplied Rome, consisting partly of rock-cut channels and partly of ruined bridges. above it is the monastery of S. Cosimato. Close to this point begins the valley of the Digentia (mod Licenza) in which Horace's Sabine farm was situated.

For a full description *see* G. Lugli in *Monumenti dei Lincei* xxxi (1924) 457 *sqq.*; and for a short account, G. H. Hallam, *Horace at Tibur and the Sabine Farm* (Harrow, 1927).

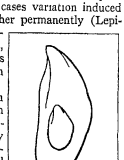
VARIATION. All kinds of living organisms vary. It is the business of the biologist to find out the range of such variation in wild and domesticated animals and plants; to decide what share of variation is due to hereditary and what to environmental causes; and to see whether heritable variations, which are the raw material of evolution, can be artificially produced in the laboratory. (*See* also SELECTION; EVOLUTION, ORGANIC; HEREDITY.) (X.)

VARIATION IN NATURE

The variation of animals and plants in nature is, so far as known, subject to the fundamental laws revealed by experiment and pedigree-breedings (*see* HEREDITY). Only by such experiments and culture is it possible to decide authoritatively how a given variation is produced and whether it is heritable or not. Nevertheless it is desirable to know—(a) the actual kinds of variation that occur in nature, (b) which of these we may assume to be heritable and (c) the effect which isolation (topographical, habitudinal, etc) and interbreeding may have on the distribution of variant characters in nature. Variation in the habits of animals, the food they eat, their breeding-seasons and all their complex inter-relationships is moreover of cardinal importance in evolutionary studies and can only be effectively observed among animals in nature The kinds of structural variation that occur in nature will be best illustrated by means of the following classification which, although it is not exhaustive, will show the circumstances in which such variation typically occurs.

1. Variation regularly occurring in the presence of a given environmental condition or factor

(a) Gross variation in form and size associated with the excess or deficiency of some tissue-forming substance.



The periwinkle, clam and mussel when living in water of reduced salinity (*e.g.*, in the Baltic Sea) are found to be smaller than in normal sea-water. Low night-temperature and inferior soil render various hawkweeds (*Hieracium*) living at high altitudes more stunted than those living at lower altitudes.

(b) Special modifications.

The tail-lamellae of the brine shrimp (*Artemia salina*) are reduced in water of high salinity. The shape of the common cockle (*Cardium edule*) is more elongate in water of salinity above

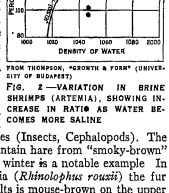
that of normal sea-water Terrestrial animals living in damp situations or in humid atmosphere are often darker than representatives of the same species which live in drier conditions This is recorded among slugs (Leydig), birds (Swarth) and mammals (Sumner) The greater part of the variation exemplified by (a) and (b) is in all probability non-heritable. Experiment has however shown that in a few cases variation induced by external causes may be inherited either permanently (Lepidoptera, *Harrison and Garrett*) or temporarily (Amphibia, *Kammerer;* Crustacea, *Agar*). Similarly the colour-differences recorded by Sumner (*see* above) have been shown to be hereditary

A series of allied varieties or races which replace each other in succession, either in time or place, will sometimes exhibit progressive modification Such variation may be simply correlated with a change in geographical position, the causes of structural change being obscure

FROM GRIMPE AND WAGLER, "DIE TIERWELT DER NORD UND OSTSEE" (AKADEMISCHE VERLAUSGESELL SCHAFT, LEIPZIG).

FIG 1—SPECIMEN OF NORTH SEA AND BALTIC MUSSELS, THE SMALL FORM BEING CHARACTERISTIC OF THE BALTIC SEA

2 Variation resulting from adaptation to diverse conditions.



In the arrow head (*Sagittaria*) the same plant may have some leaves adapted for aerial and others for aquatic conditions. Protective "mimicry" affords some striking examples of this type of variation among animals (*see* MIMICRY).

3. Variation known to be heritable but not referable to known external causes

Many variations in colour, form and pattern that are known by experiment to be hereditarily stable have been recognized in nature Such variations may be distributed at random through a large natural population, or the latter may be divided into topographically isolated races or colonies, each of which has a more or less distinct appearance. These divergences may likewise be associated with other modes of isolation, *e.g*, with mutual sterility, difference in breeding-period, etc. Other examples of this kind of variation are to be found in the "colour-phases" of mammals (*e g*, foxes) and birds Stresemann's important work on the occurrence and heredity of such colour-phases in the latter should be consulted (Bibliography). It is also known in flowers.

4. Variation due to accident, interference with growth-processes, etc.

It is not always easy to differentiate between this type of variation and that described in (1). For example the shells of the water snail *Planorbis* seem to assume the uncoiled ("scalariform") form in water of unusually high temperature. This may be described as an accidental malformation, but it is actually produced by a particular state of the medium in which these snails live. Scalariformity is more obviously "accidental" when produced in the Gastropod *Trochus* by parasitic infection. Plant lice sometimes produce green colour in flowers and the attacks of a rust fungus (*Aecidium*) produce shorter and broader leaves in *Euphorbia cyparissias*

FROM THOMPSON, "GROWTH & FORM" (UNIVERSITY OF BUDAPEST)

FIG. 2—VARIATION IN BRINE SHRIMPS (ARTEMIA), SHOWING INCREASE IN RATIO AS WATER BECOMES MORE SALINE

5. Seasonal Variation.

This is a familiar phenomenon among vertebrate animals, and is also known among invertebrates (Insects, Cephalopods). The change of coat-colour in the mountain hare from "smoky-brown" in summer to white or "blue" in winter is a notable example In the rufous horseshoe bat of India (*Rhinolophus rouxii*) the fur after the spring and autumn moults is mouse-brown on the upper surfaces. This changes in course of time into brighter colours, probably owing to oxidation of the pigment.

6 Variation due to sexual dimorphism and growth-changes

Strictly speaking this should not come under the rubric of variation as described here; but it is important to notice that some of the differences in size, colour and shape among animals of the same species may be due to these causes

The data presented above relate only to the structure of animals and plants Although the distinction between structural characters and those of physiological constitution and habits is arbitrary, it is convenient to retain the distinction in a survey of this kind. Our knowledge concerning modes of variation other than that of structure is less complete. Each species is probably as variable in its physiological constitution as it is in its structure This has been shown by exact tests, and also may be inferred from such facts as the infection of hosts belonging to different families and genera by individuals of the same species of parasite, the occupation by members of the same species of habitats radically different in physical and bionomic factors, varying susceptibility to disease and so on. The variability of habits may be illustrated by Darwin's observations on the behaviour of the great titmouse, certain individuals of which species sometimes behave as birds of prey.

A number of highly important considerations are omitted from this discussion The problem of intermediacy, the degree of variability in different species of the same genus, the relation between natural variation and classificatory units, observations on the effect of Natural Selection and on the first appearance, increase or decrease of variant individuals are dealt with in the undermentioned works

(G. C. R.)

of the *variation* which actually occurs, *differences* in heredity or *differences* in environment?" If, now, we take variation in the larger sense, to include differences between all living things, it is obvious that, all in all, differences in environment are an insignificant cause of the existng variation as compared with hereditary differences, and this is usually true even of two individuals chosen from closely related yet different species. On the other hand, within a given population of one species, the variation due to environment is sometimes comparable to, or even much greater than, that dependent on the genes. Which sort of variation predominates, and to what extent, will depend on many circumstances, and to answer our question will therefore require separate study, and often elaborate experimentation and measurement, in the case of each population considered and even in the case of different characteristics in the same population. The unravelling of any intimate combination of hereditary and environmental effects will usually demand either that we hold the effective features of the environment constant (often an impossible operation), or else that we secure a set of individuals identical in their genes (as a result of inbreeding, twinning or asexual reproduction); under such circumstances the residual variation, due to the influence that was not held constant, may then be ascertained.

It is especially desirable to discover not only the extent of variation due to environmental differences, but the principles governing the production of this variation. This quest, however, leads to a study of all the intricacies of embryonic development, physiology and mechanistic biology in general. Although the details of the chemistry and physics comprised in these phenomena are for the most part scarcely guessed, we at least know, from our observations on the grosser visible occurrences, that the processes whereby most adult organs and characteristics are formed are highly involved, interdependent in a complicated way and composed of many successive reactions. Make one change, and effect follows effect until the final result bears no resemblance to the initial one. So, for example, a quantitative change in some primary process may appear in the adult as a qualitative change, and vice versa. It should also be observed that there are often regulatory mechanisms which automatically compensate for effects produced, as in regeneration of a lost limb or in the accelerated growth of a child following temporary stunting.

Genetics has adduced cogent evidence that, despite the strong influence of the environment in modifying the body as a whole, and even the protoplasm of its cells, the genes within the germcells of that body retain their original structure without specific alterations caused by the modification of the body, so that when the modified-individual reproduces it transmits to its offspring genes unaffected by its own "acquired characters." The offspring, then, will not tend to repeat the parental modifications, unless the same peculiar environment is itself repeated. Our sins and our successes are not reborn in our children, though the latter may inherit our original tendency and capacity for these. Modifications, therefore, unlike mutations, cannot be a cause of biological evolution or degeneration. Now, if modifications acquired before the conception of children are not visited upon the latter, it certainly holds true that any modifications acquired by the mother after the embryos are partly developed, but prior to their birth, would not be transmitted to them. Mothers may rest assured that there is no more ground either *a priori* or in observation, for supposing that a fright received during pregnancy (or before) will give their child a fearsome disposition than that it will give him spots.

Variation Due to Segregation and Recombination of Genes.—Whenever an individual breeds, having received a different hereditary contribution from its two parents, its offspring will tend to vary from one another. Thus, if we had received a gene for brown eyes from our mother, and one for blue eyes from our father, then, although we ourselves would have brownish eyes (brown being said to be "dominant" and blue "recessive"), nevertheless we would transmit our gene for brown only to half of our reproductive cells, and the gene for blue, unalloyed by brown, to the remainder. This process of separation is called segregation (*see* HEREDITY). If our parents had given us different genes for hair-form also, we would produce reproductive cells having all the possible assortments of the two pairs of genes, namely, some having "brown curly," others "blue straight," still others "brown straight" and the rest "blue curly." This phenomenon is recombination. Since such variation can be produced in our children only in respect to genes which already differed from one another in our parents, it is evident that the primary cause of this variation lies in the events whereby these genes came to differ in the first place, that is, in the gene-mutations such as originally changed a gene for brown eyes into the gene for blue. These mutations, that make possible the recombinations of to-day, may have happened in the remote past.

The explanation of segregation and recombination is to be found in the behaviour of the chromosomes, those tiny separate filamentous bodies, visible under the microscope, which contain the invisible genes "linked" together within them, like beads in so many separate chains. Several or many chromosomes, each probably containing hundreds of different genes of distinctive natures and effects, are contained in each of the two uniting reproductive cells derived from the two parents. While the majority of the genes from one parent are always like those from the other, since the parents are in general similar organisms, yet in the case of most matings there are some gene-differences, and these give an opportunity for the operation of the segregation and recombination processes above mentioned, after the individual formed by the union of the two cells in question develops and reproduces reproductive cells for a still later generation.

It will be seen that the more gene-differences exist the more different combinations can then be formed. The numerical relations resulting from recombination are calculable according to definite laws, provided the effects of the genes concerned, and their positions in the chromosomes, have been determined by prior experimentation. The character-effects of untried combinations cannot, however, be predicted with certainty, as unexpected developmental results, including even new traits, are occasionally produced by recombination. As some new combinations may be more advantageous for the race than the original combinations, the function of recombination, of segregation, and in fact of sexual reproduction itself, becomes explained in terms of their value in evolution.

The development of most characters depends on the combined action of numerous genes. A difference in any one of these genes may affect either the quality, or the degree of development of the character in question. Now, when a number of mutations, in different genes all concerned with the same character (*e.g.*, stature), have some time previously occurred in a population, random crossing and recombination will result in the transmission, to different offspring, of many different assortments of the mutated and non-mutated genes. Thus the population may tend to exhibit many different grades of expression of the character. These grades will often differ only by small steps, which become blurred into an apparently continuous gradient through the effect of environic modifications. Such quantitative variation, as well as all other variation of recombinational origin, is of course especially evident when individuals are bred which resulted from the crossing of widely different stocks, in which many differing gene-mutations had become established since these stocks diverged from their common ancestor.

Many abnormal types of recombination occasionally occur, owing to such disturbances of chromosome-behaviour as the loss or reduplication of a chromosome or section of a chromosome, or the reduplication of one or more entire sets of chromosomes. When such an occurrence alters the proportions existing between the different kinds of genes (by changing the numbers of some and not of others) there generally results a combination of various (usually detrimental) abnormalities at once. At other times, a chromosome may become broken in two, or two chromosomes unite to form one, or a piece broken off one chromosome and united to another. The genes thereby become rearranged, but the characteristics of the individual probably remain little affected, since they depend rather on the kind and numbers of

different genes present than on their arrangement X-rays, cold and other influences are known to induce such disturbances of chromosome behaviour

Mutations in the Genes.—It has been found in fruit flies (*Drosophila*) that any given gene, existing in a fly at the present day, has probably remained constant in its composition for several thousand years. This stability is not passive, for, as every organism grows and reproduces through a process of repeated cell growth and cell division, each gene must repeatedly reproduce itself, and in so doing it must each time construct a daughter-gene that possesses exactly its own peculiar structure. Occasionally, however, something goes wrong, and either the mother-gene becomes altered in its composition or else the daughter-gene is not formed exactly in the image of the old gene As a result of this mutation there arises a new type of gene, having a different effect upon the organism, and this mutant gene is then capable of reduplicating its own new type—a process which it usually performs with as constant accuracy as that which the old gene had exhibited It is this peculiarity of the gene—its retention of the power of self reduplication despite the occurrence of alternations (mutations) in its composition—which makes heritable variations possible, and hence organic evolution.

There is evidence that, when one gene in a cell mutates, the thousands of others, even including the similar or identical gene derived from the other parent, remain unaffected and constant The mutation, then, may be regarded as an "accident" of submicroscopic dimensions, dependent on the occurrence of certain "chance" configurations of atoms, electrons and energy-quanta within or near the gene in question It is not strange, in view of this, that it has not yet been proved possible, by particular external conditions, to dictate the occurrence of specified types of gene mutations in preference to others.

Though the kind of mutation which shall occur has not been brought under control, experiments with a number of different organisms have shown that heavy treatment with X-rays will make the mutational accidents in general occur far more frequently than otherwise, so that gene mutations of varied kinds may be produced at a rate in some cases more than a hundred times higher than that at which they previously were found to occur This raises the conjecture, as yet untested, that possibly the γ-rays (related to X-rays) which originate in minerals of the earth's crust have played an essential role in the causation of the varied "natural" mutations through which evolution has come about However, there is evidence that temperature, genetic composition, and perhaps other factors, also affect the general frequency of gene mutations No particular stage in the life cycle is known to be especially favourable for the occurrence of gene mutations; certainly they may happen either in embryos or in adults, and in somatic as well as in germinal tissue, though of course only mutations in germ cells can be inherited

Though most gene mutations seem, in the sense above explained, to be accidents, some genes appear to be less stable than others, and a few are definitely known to be exceedingly mutable (ever-sporting) In the latter cases, which may represent changes of a different sort from most gene mutations, the stability of the mutable gene may be much affected by specific conditions. These effective conditions differ in different cases Some are determined by the nature of the tissue and developmental stage in question, others by the external environment, and still others by the genetic composition.

A given gene has the capability of mutating in various ways so as to form a number of different kinds of genes (multiple allelomorphs). Usually the effects of these differing changes in a given gene resemble each other strongly, and often, though not always, the discernible differences between them lie chiefly in the degree of change produced There are also numerous cases on record of mutations that seem quite identical in kind with other mutations which occurred independently in homologous genes of other individuals belonging to the same or a related species. Not infrequently, too, different kinds of genes (nonhomologous) will, on mutating, produce similar or indistinguishable final effects on the characteristics of the organism. In this connection it is found that certain character changes can be produced by mutations in a greater number of different genes, and hence tend to occur more commonly, than others.

The most frequently produced effect, so far as known, is the lethal effect; that is, mutant genes are usually so deleterious in their action that they tend to kill the organism. When they are not positively lethal they are usually retrograde in direction, and hinder rather than help the organism to fulfil the functions of its existence. Such results are to be expected of accidental changes occurring in any complicated organization. A race, therefore, will tend gradually to undergo degeneration in any respect in which selection (natural or artificial) does not persistently weed out the degenerative mutations that continue to occur It can be only the rare mutations that are helpful which furnish material for evolution. These latter, however, when they show, will tend to multiply.

As a matter of fact, most gene mutations never show. For most (though not all) mutant genes are recessive to the type from which they arose, and in their cases an obviously mutant individual cannot appear unless—usually many generations subsequently to the original gene mutation—two reproductive cells, each bearing the identical mutant gene, meet in fertilization

Both conspicuous and inconspicuous, minor and major, fundamental and superficial character changes are produced by gene mutation, and either one character or several at once may be altered by a single gene change. The more far-reaching the change, the more apt it is to be deleterious rather than advantageous. Hence geneticists are returning to a view essentially similar to Charles Darwin's (though now much more highly elaborated), namely, that the origin of one species from another usually involves the accumulation of numerous selected small steps of heritable variation.

VARIATIONAL PSYCHOLOGY: *see* Differential Psychology.

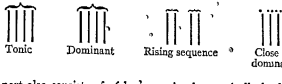
VARIATIONS, in music, the term given to groups of progressively developed versions of a complete self-contained theme, retaining the form of that theme though not necessarily its melody This is the classical sense of the term, but there are modern developments of the variation form to which this definition is at once too broad and too precise to apply. The aesthetic principle of variations appeared at very early stages of music. During the 16th century an artistically mature variation form automatically rose in the polyphonic treatment of Gregorian hymns verse by verse. Accordingly, the hymns and Magnificats of Palestrina might be described as contrapuntal sets of variations on ecclesiastical tunes, like rich and free examples on the simple plan shown later by Haydn's variations on his Austrian national anthem in the "Emperor" quartet (opus 76, no 3). Already in the 16th century instrumental music was climbing up the trellis of a primitive variation form. A favourite plan (*see* the *Fitzwilliam Virginal Book, passim*) was to put together several popular or original tunes, with an ornamental variation sandwiched between Sometimes sets of variations on a single tune were produced with excellent effect, as in Byrd's variations on "The Carman's Whistle." Such variations were naturally grouped in order of increasing brilliance, and they often include passages that would catch the greatest pianoforte players.

In the 17th century a highly artistic form of variation solved with great simplicity the problem of expanding instrumental pieces to a length admitting of growth to a big climax. This was the ground bass, a single phrase placed in the bass and repeating itself ad infinitum. It originated in the dance forms of the *passacaglia*

and the *ciaconne*. Both were in slow triple time, the chaconne having a strong accent on the second beat, while the passacaglia, by some chance, developed the liberty to transfer its theme to other parts than the bass. The genius of Purcell was cruelly hampered by the non-existence of large musical forms in his time, and he seized upon the ground-bass with avidity. By the time of Bach and Handel lighter sets of variations, consisting essentially of embroidery on a melody, had come into vogue. Bach's *Aria variata alla maniera Italiana* tells us where this fashion began; and in France the *air et doubles* was taken over from early English virginal music. Doubles are variations each of which divides the rhythm into quicker notes than the one before. The most familiar example is that known as "The Harmonious Blacksmith" in Handel's E major suite. Sometimes the air itself was stated in a tangle of ornamentation, while the doubles simplified the melody and varied the accompaniment. But Bach had meanwhile applied the principle of the ground-bass to variations on a complete symmetrical movement in binary form. His Air and 30 Variations, commonly known as the "Goldberg" variations, is (with the exception of Beethoven's 33 *Veranderungen* on a waltz by Diabelli) the most gigantic set of variations in the world. A melodically interesting ground-bass could not be maintained on so large a scale; but the 32 bars of Bach's theme are so many clear harmonic steps which can be represented by many analogous progressions, without loss of identity. (Ex 1a.) There is no question of retaining or varying the melody of the aria, which is a tissue of ornaments that will bear neither development nor simplification.

Ex 1a. Harmonic theme. (BACH. *"Goldberg" Variations.*)

Ex. 1b.
Var. 25.



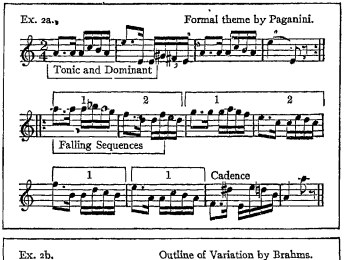
The rise of the sonata style again brought the melodic embroidery variation into prominence; for in sonata forms we identify themes entirely by their melodies. Now, with not more than three or four exceptions, the best sets of variations by Mozart and Haydn are movements in their sonata works; and their independent sets are either early or perfunctory exercises and encore-pieces. Two common mistakes of professional and amateur criticism are, first, the judging of Haydn's and Mozart's variations by these parerga, and secondly, the much graver error of despising the embroidery variation on principle. It is either vulgar or sublime. And it is handled lovingly by precisely the greatest masters of deep harmonic and rhythmic variation, Beethoven and Brahms. Haydn is fond of a special form first known in Philipp Emanuel Bach. It consists of alternating variations on two themes, alternately major and minor; the first a rich and complete binary melody, and the other a shorter binary melody, often beginning with the same figure as the first. The first theme usually returns as if it were going to be unvaried, but its first repeat is an ornamental variation. The form is rarely worked out far enough to include more than one variation of the second theme; and sometimes (as in the famous "Gypsy" trio) there are new episodes instead of variations of the second theme, so that the form becomes a sectional rondo. The only strict example of Haydn's type of alternating variations in later music is the first allegretto of Beethoven's pianoforte trio in E flat (op 70, No. 2); but a magnificent application of it, without change of mode, though with a wide range of key, is shown in the slow movement of his C minor symphony.

Beethoven, in his last works, invented another variation-form on two themes, of which the second is in a different key and time. The examples of this are the slow movement of the 9th symphony and the Lydian figured chorale in the A minor quartet. In the slow movement of Brahms's F major string quintet (op. 88), the alternation of the two keys gives rise, in the last line of the movement, to one of the most astonishing dramatic strokes in all music. Beethoven uses embroidery variations as means of obtaining extraordinary repose in slow movements. The extreme case of this is the slow movement of the sonata op. 57 (commonly called "Appassionata"), which is described in the article on SONATA FORMS. In this, and in many other instances, his method is that of the *air et doubles*, which grows to a natural climax which can subside into the rhythm of the plain theme. Until his latest works, such sets of variations are never finished. Their dramatic intent is that of a repose which is too unearthly to last; and at the first sign of dramatic motion or change of key the sublime vision "fades into the light of common day," a light which Beethoven is far too great an idealist to despise. *See* the andante of the B flat trio (op. 97); and the slow movement of the violin concerto, which contains two episodic themes in the same key. In his later works Beethoven found means, by striking out into foreign keys, of organizing a coda which finally spins down in fragmentary new variations, or even returns to the plain theme. Thus he was able to end his sonatas, opp. 109 and 111, with solemn slow movements.

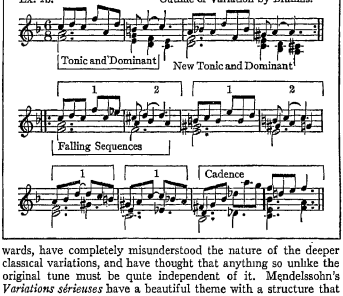
Beethoven also found other applications of the variation forms. Thus the finale of the Eroica symphony has not only the theme but many other ideas in common with the brilliant set of variations and fugue for pianoforte on a theme from *Prometheus* (op 35); and the fantasia for pianoforte, chorus and orchestra, and the choral finale of the 9th symphony, are sets of melodic variations with freely-developed connecting links and episodes. In the case of the 9th symphony, a second thematic idea eventually combines with the figures of the first theme in double fugue.

But Beethoven's highest art in variation-form is independent of the sonata. From his earliest display of pianoforte playing, the wonderful 24 variations on a theme by Righini, to his supreme variation-work, the 33 on Diabelli's waltz, he uses and transcends every older means of variation and adds his own discoveries. Before Beethoven the basis of variations might be a ground bass, a melody or a harmonic scheme. Beethoven discovered that rhythm and form can, with a suitable theme, be a solid basis for variations. The aria of Bach's Goldberg variations is in its phrasing as uniform as a chess-board; and if its harmonies had not a one-to-one correspondence with each variation the form would be lost. But there are themes, such as Haydn's Chorale St. Antoni, which Brahms varied, where the phrasing is interesting in itself. A similar example is the theme by Paganini (Ex. 2a) which inspired Brahms to compose two complete sets on it.

The climax in the history of variations dates from the moment when Beethoven was just about to begin his 9th symphony, and received from A. Diabelli a waltz which that publisher was sending round to all the musicians in Austria, so that each might contribute a variation to be published for the benefit of the sufferers in the late Napoleonic wars. Diabelli's theme was absurdly prosaic, but it happened to be, perhaps, the sturdiest piece of musical anatomy that Beethoven (or any composer since) ever saw; and it moved Beethoven to defer his work on the 9th symphony! The shape of Diabelli's waltz may be illustrated by a diagram which represents its first 16 bars; the upright strokes (not the spaces) being the bars, and the brackets and dots (together with the names underneath) indicating the rhythmic groups. The sec-



ond part also consists of 16 bars, moving harmonically back from the dominant to the tonic, and rhythmically the same as the first part. This plan is astonishingly elastic. The alternation of tonic and dominant in the first eight bars may be represented by another familiar form in which three bars of tonic and a fourth of dominant are answered by three bars of dominant and a fourth of tonic; as in variation 14 (which must be reckoned in half-bars). Again, when the theme answers the tonic by the dominant it raises the first melodic figure by one step, and this may be translated by the answer on the supertonic harmony. In the course of 50 minutes a few of these 33 variations become vague as to more than the beginnings and cadences of the theme; and there are three simple variations in which one would like to ask Beethoven whether he had not inadvertently omitted a bar; but the momentum of the theme is never lost; and after a group of three slow and rather free variations this momentum breaks into an entirely free fugue (variation 32) on a salient feature of what must by courtesy be called Diabelli's melody. A free fugue is a favourite solution of the problem of the coda in a set of variations The momentum produced by the revolution of true variations in the orbit of the theme gives the key to the whole problem. A fugue solves it by flying off at a tangent. Very sublime is the way in which Beethoven, after letting his fugue run its torrential course, returns to the orbit of his theme in an ethereal little minuet with a short coda of its own which, 16 bars before the end, shows signs of beginning to revolve again.



Again, let us regard the period of the theme not as an orbit but as diurnal rotation. We can then describe the codas of Brahms's Paganini-variations as produced by accelerating the spin till it breaks away for a while and then resumes for a few final catastrophic whirls; exactly like a dying top (though this, of course, does not accelerate its spin). Without acceleration Beethoven ended his wonderful C minor variations (most perfect of passacaglias) in this way. Brahms found in Haydn's Chorale St. Antoni the opportunity for another method. He took the first five bars as a ground-bass, within which narrow orbit the finale moves until its climax broadens out into the rest of the glorious theme, and so rounds off the whole work.

Bach poised the contrasts and climaxes of the Goldberg variations so accurately that the ending of the whole by a simple *da capo* of the theme is astonishingly effective. It is as if a charming old ancestress of a living line of great folk were to step from the frame of her Holbein portrait and bow to her assembled posterity.

To speak of the progress in variation-form since Beethoven is like speaking of the progress in reinforced concrete since the Parthenon. The classical variation-form is limited only by the composer's imagination and technique; and the removal of its foundations does not enlarge it at all. There is no reason to condemn other kinds of variation; and many great and beautiful works in non-classical variation-form exist, from Schumann's *Études Symphoniques* to Elgar's "Enigma" variations and Dohnányi's *Variations on a Nursery Tune*. But no "free" variation that breaks down the phrasing of its theme and follows its own discursive ways will ever achieve anything externally so unlike the theme as a strict harmonic and rhythmic variation on classical lines. (*See* Ex. 2b.) Nor will a series of such variations acquire anything like the classical momentum. On the contrary, in clumsy hands the free variation becomes apologetic in the way in which it offers raw chunks of the original melody as evidence that it has not forgotten its duty, like Lewis Carroll's poetic *Tema con Variazioni*, the preface to which is an unconscious epitome of modern misunderstandings of the form.

Variation writers may be scientifically classified into those who know their theme and those who do not. There is no reasonable doubt that many very clever composers, from Mendelssohn on-

wards, have completely misunderstood the nature of the deeper classical variations, and have thought that anything so unlike the original tune must be quite independent of it. Mendelssohn's *Variations sérieuses* have a beautiful theme with a structure that might have given rise to splendid features; but Mendelssohn simply ignores this structure and replaces it by weaker things in almost every variation. Schumann shows more insight. He has no great grip of his theme, but he tries to distinguish by titles those variations which are true from those which are episodic; thus in the *Études Symphoniques* the etudes are numbered separately from the variations; the andante of the F major quartet is called *quasi variazioni*; and the strictest set he ever wrote (on a theme by Clara Wieck) is called Impromptus.

Brahms stands alone in his grip of his theme. Reger is no nearer the classical form in his variations than in his other works The present state of the form seems to indicate that if the composer does not aim at strict variations his most vital results will be on the line of melodic development, as in the above-mentioned works of Elgar and Dohnányi, the Symphonic Variations of Dvořák, and those variations of Reger which are closest to this type. (D. F. T.)

VARIATIONS, CALCULUS OF: *see* CALCULUS OF VARIATIONS.

VARICOSE VEINS. Varicose veins is the term usually applied to enlarged, dilated and tortuous superficial veins of the lower extremity The condition is one of the most common human ailments which is amenable to surgical treatment. It has been recognized since the time of Hippocrates and probably dates back to the time when man first assumed the erect position. The disease has never been recognized in quadrupeds.

The most important causative factor is the hydrostatic pressure of the blood in the veins (*q* v.) in the erect position. Normally, there are bicuspid valves in the veins which permit the blood to

flow only toward the heart. Because of the segmental arrangement of this system of valves, the venous pressure becomes greatly lowered during muscular activity

In most instances of varicose veins, there is apparently a defective system of valves in the upper part of the extremity so that with increasing age the veins become more dilated Eventually, the entire system of veins, down to and including those over the foot, becomes dilated and tortuous. There is a definite hereditary factor in the disease. It is also believed that occupations which require a great deal of standing, or even sitting with little muscular activity in the lower extremities, are chief causative factors.

Abdominal tumours, especially the pregnant uterus, which increase pressure within the abdomen and thereby interfere with the return of blood from the extremities, may also play a role An additional contributing factor during pregnancy may be one of the hormones (not identified at mid-20th century). The veins of the legs frequently become greatly dilated before the uterus has enlarged to any great extent.

Varicose veins rarely are a serious threat to life or limb. Treatment is sought frequently because of the disfiguring appearance The most common symptom is pain in the region of the dilated veins

In cases of long-standing varicosities, changes may develop in the skin, resulting in a chronic irritation known as varicose eczema or dermatitis which may even progress to chronic ulceration In a few instances when the veins are very large, the individual may complain of faintness and a rapid heart beat, the result of the pooling of a large volume of blood in these venous reservoirs

Spontaneous clotting may develop because of the stagnation of the blood, resulting in a condition called venous thrombosis or thrombophlebitis. In rare instances, a varicose vein may rupture with considerable loss of blood Bleeding under these conditions can be quickly controlled by elevating the leg above the level of the heart and applying a pressure pad over the bleeding point.

The treatment of varicose veins has gone through many cycles At mid-20th century the most satisfactory method yet developed consisted of removing the main venous trunks, the internal and external saphenous veins, by surgery. This is performed through a few incisions and is accomplished by a process of subcutaneous stripping of the veins. The complications of this form of treatment, if it is performed carefully, are very few and the results excellent. The simple types of varicose ulcer, a complication of varicose veins, are also curable by this method of treatment. Attempts to cure the condition by the injection of sclerosing solutions alone have not been successful.

The time-honoured use of an elastic stocking or bandage may give relief from pain but is not curative. It may be recommended, however, in aged patients who are not fit subjects for a surgical operation.

VARIETY THEATRE: *see* THEATRE.

VARIOLITE, in petrology a basaltic or doleritic rock with prominent spheruliţic (variolitic) texture, the spherulites or varioles consisting usually of radial aggregates of feldspar. These varioles, especially on weathered surfaces, appear as pale-coloured spots, giving the rock a pockmarked appearance. The name is from Lat. *variola*, smallpox, in allusion to this characteristic feature

The variolitic texture of the basic rocks is closely akin to the spherulitic texture of the acid lavas, as seen in rhyolites, etc.

Variolites frequently form the tachylytic selvages of dolerite dikes (*see* TACHYLYTE), and also appear in the form of pillow lavas (*see* SPILITE). The varioles are usually rounded in outline and are often about ¼ in. in diameter, but may much exceed this size With few exceptions they are built up of divergent fibres of feldspar embedded in dark brown glass. As varioles are frequently much decomposed, the glassy matrix is represented by secondary alteration products or has been devitrified. (C. E. T.)

VARLEY, JOHN (1778–1842), English water-colour painter, was born at Hackney, London, on Aug 17, 1778. His father discouraged his leanings toward art, and placed him under a silversmith But after his father's death the lad found work with an architectural draughtsman, who employed him to sketch the principal buildings in the towns they visited. His spare hours were employed in sketching from nature, and in the evenings he was permitted, like William Turner and Thomas Girtin, to study in the house of Thomas Monro

In 1798 he exhibited his first work, a "View of Peterborough Cathedral," in the Royal Academy

In 1799 he visited north Wales, and in its wild mountain scenery found the subjects best suited to his brush. He returned to the same district in 1800, and again in 1802, and the impressions then received powerfully influenced the whole course of his art In 1804 he became a foundation member of the Royal Society of Painters in Water-Colours, and he contributed more than 40 works to its first exhibition

He had married in the previous year, and, in order to provide for the wants of an increasing family, he produced for the dealers much work of a slight and commonplace character. He also taught drawing, and some of his pupils, such as John Linnell and William Hunt, afterward became well-known.

He was a firm believer in astrology and casted horoscopes It was at his house that his friend William Blake sketched his celebrated "Visionary Heads." Varley died at London on Nov. 17, 1842.

Varley's landscapes are graceful and solemn in feeling and simple and broad in treatment, being worked with a full brush and pure fresh transparent tints, usually without any admixture of body-colour.

Though his works are rather conventional they are excellent in composition Some of his earlier water-colours, including his "Views of the Thames," were painted upon the spot, and possess greater individuality than his later productions, which are mainly compositions of mountain and lake scenery, produced without direct reference to nature.

Among his literary works are *Zodiacal Physiology* (1828), *Observations on Colour and Sketching from Nature* (1830); and *A Practical Treatise on Perspective, and Principles of Landscape Design for Young Artists.*

VARNA (STALIN), a fortress, seaport, district capital and episcopal city of Bulgaria, on the Stalin gulf, an inlet of the Black sea, in 40° 12′ N. and 27° 56′ E. Pop (1947) 77,792. Varna is built on the hilly north shore of the bay, overlooking the estuary of the Devna river It is the eastern terminus of the railway to Rustchuk and Sofia. The "Varna quadrilateral," so important in Bulgarian military history, consists of the fortresses of Varna, Shumla, Rustchuk and Silistra (*q.v.*). Varna ranks with Burgas as one of the two principal seaports of Bulgaria. Its deep and capacious bay is sheltered from northerly and northeasterly winds, and the harbour works are modern

The principal exports include cattle and dairy produce, grain, lamb and goat skins, and cloth (*shayak*); the imports include coal, iron and machinery, textiles, petroleum and chemicals. The headquarters of the Bulgarian Steamship Co, which traded with Turkey, Greece and Russia, were established there. Its trade was affected by the cession of the Dobruja to Rumania until 1940, but it became a popular seaside resort. During World War II, Germany used the port as a shipping supply base to provision axis armies fighting in the U.S.S.R

Varna was the ancient Milesian colony of *Odessos*, founded 585 B.C. Close by was fought in 1444 the battle in which Murad II slew Wladislaus III of Poland and Hungary, and routed his forces under Hunyadi János. Varna was occupied in 1828 by the Russians, in 1854 by the allies, who there organized the invasion of

the Crimea, and in 1877 by the Egyptian troops summoned to the defense of Turkey against the Russians. By the treaty of Berlin (1878) it was ceded to Bulgaria. Long the seat of a Greek metropolitan, it became in 1870 the seat of a Bulgarian bishop.

In 1949 it was renamed Stalin and made the capital of a newly formed district of the same name.

VARNHAGEN VON ENSE, KARL AUGUST (1785–1858), German biographer, was born at Dusseldorf on Feb. 21, 1785. He studied at Berlin, Halle and Tübingen. He began his literary career in 1804 as joint-editor with Adelbert von Chamisso (*q.v.*) of a *Musenalmanach*. In 1809 he joined the Austrian army, and was wounded at the battle of Wagram. Soon afterward he accompanied his superior officer, Prince Bentheim, to Paris, where he carried on his studies. In 1812 he entered the Prussian civil service at Berlin, but in the following year resumed his military career, this time as a captain in the Russian army. He accompanied Tettenborn, as adjutant to Hamburg and Paris, and his experiences were recorded in his *Geschichte der Hamburger Ereignisse* (London, 1813), and his *Geschichte der Kriegszüge des Generals von Tettenborn* (1815). At Paris he entered the diplomatic service of Prussia, and in 1814 acted under Hardenberg at the congress of Vienna. He also accompanied Hardenberg to Paris in 1815. He was resident minister for some time at Karlsruhe, but was recalled in 1819, after which, with the title of "Geheimer Legationsrat," he lived chiefly at Berlin. He had no fixed official appointment, but was often employed in important political business. In 1814 he married Rahel Levin (1771–1833) sister of the poet, Ludwig Robert (1778–1832). By birth she was a Jewess, but before her marriage she made profession of Christianity. She was a woman of remarkable intellectual qualities, and exercised a powerful influence on many men of high ability. After her death her husband published a selection from her papers, and afterward much of her correspondence was printed. Varnhagen von Ense died suddenly in Berlin on Oct. 10, 1858.

He made some reputation as an imaginative and critical writer, but he is famous chiefly as a biographer. He possessed a remarkable power of grouping facts so as to bring out their essential significance, and his style is distinguished for its strength, grace and purity.

BIBLIOGRAPHY.—Among his principal works are *Goethe in den Zeugnissen der Mitlebenden* (1824); *Biographische Denkmale*, 5 vol (1824–30), 3rd ed. (1872); and biographies of General von Seydlitz (1834), Sophia Charlotte, queen of Prussia (1837), Field-Marshal Schwerin (1841), Field-Marshal Keith (1844), and General Bülow von Dennewitz (1853). His *Denkwurdigkeiten und vermischte Schriften* appeared in 9 vol. (1843–59), the two last volumes appearing after his death. His niece, Ludmilla Assing, between 1860 and 1867, edited several volumes of his correspondence with eminent men, and his *Tagebucher*, 14 vol (1861–70). *Blatter aus der preussischen Geschichte* appeared in 5 vol (1868–69); his correspondence with Rahel in 6 vol (1874–75); and with Carlyle (1892). His selected writings appeared in 19 vol. in 1871–76. There is also an extensive literature dealing with Rahel Varnhagen von Ense; see especially her husband's *Rahel, ein Buch des Andenkens*, 3 vol (1834); *Aus Rahels Herzensleben* (1877); E. Schmidt-Weissenfels, *Rahel und ihre Zeit* (1857); *Briefwechsel zwischen Karoline von Humboldt, Rahel und Varnhagen von Ense* (1896); O Berdrow, *Rahel Varnhagen* (1900).

VARNISH. Varnish is a homogeneous organic composition which, when thinly spread in liquid form, dries on exposure to air or to heat to a hard transparent film which decorates and protects the surface to which it is applied. The decorative effect is sometimes enhanced by incorporating soluble dyes or transparent pigments, to form colour varnishes; or varnishes may be used as the "vehicles" or binders in opaque pigmented compositions; *i.e.*, enamel or paint (*qq.v.*).

Varnish dates from prehistoric times. The ancient Egyptians melted soft resin, such as sandarac, mastic or pitch, with oil to form a varnish which was applied warm with the finger or a knife (precursor of modern "hot-melt" varnishes). On the mummy cases in the British Museum the varnish still retains its lustre, with surface uncracked and undamaged. Theophilus, in the 11th century, told how to make an oil varnish by dissolving molten resin in hot oil; but the first description of a linseed-oil varnish thinned with oil of turpentine, with litharge as a drier, appeared about the middle of the 18th century.

Varnishes are composed in general of four kinds of ingredients: (1) resins or gums, to impart hardness and lustre; (2) drying oils, to add flexibility and toughness; (3) volatile solvents, to thin the varnish to suitable consistency for application, and (4) driers and other modifiers, to hasten the drying rate, control the lustre, etc. Oil (or oleoresinous) varnishes usually contain all four of these, but one or more may be omitted. Lithographic varnishes, also sometimes called stand oils, consist simply of linseed oil (or, rarely, another drying oil), thickened by polymerization at about 270°–315° C. for varying periods according to the final viscosity desired. Largely used in both lithographic and typographic printing inks, they illustrate a type of varnish with only one kind of ingredient, and stand at infinity on the scale of length (measured by the number of gallons of oil per 100 lb. of resin). However, even the drying oil is replaced in some modern oil varnishes (then more properly called synthetic-resin varnishes) by a flexible alkyd or similar resin. Upon application of oil varnishes, the volatile solvent (if present) evaporates and leaves a soft film of oil (and resin) which subsequently dries or solidifies by absorbing oxygen from the air and polymerizing to more complex molecules.

At or near the zero end of the scale of length are the spirit varnishes, which are solutions of resins or cellulose compounds in a volatile solvent. Hard, dry, but often somewhat brittle, resinous films remain upon evaporation of this solvent. The term lacquer is commonly used in the English-speaking world for spirit varnishes based on nitrocellulose or other cellulose compounds, (or, in recent practice, on vinyl, acrylic or amide polymers), whether clear or pigmented. Entirely different in composition from these are the much older oriental lacquers. The name is derived from lac (the resinous secretion of the lac insect, *Tachardia lacca*), which from ancient times was used in India in molten form to produce lacquered ware; in China and Japan lacquer was the name given to the film formed by the sap of the Tsi-chou tree (*Rhus vernicifera*), a milky emulsion which has the peculiar property of hardening only in a moist atmosphere. Employed usually in numerous thick coats, these Chinese and Japanese lacquers attain a remarkable degree of hardness, lustre and durability. In some of their characteristics the cellulose lacquers closely approach them.

Asphaltum varnishes or black japans (*see* BLACK VARNISH) may be either of the oil or spirit type, the light-coloured resin being replaced by bitumens such as gilsonite, manjak or Egyptian asphaltum, or still residues (sometimes blown, or thickened by bubbling air through them) from distillation of petroleum or of fatty acids (stearine pitch). Varnishes of another small class, called hot-melt, containing no solvent, are solid at ordinary temperatures; liquefied by heating and applied as molten fluids, they return to the solid state on cooling without requiring either evaporation, oxidation or polymerization.

Water-thinned varnishes form a class which grew rapidly in importance during World War II when nonflammable binders were needed for paints to be shipped in concentrated form and thinned with water.

The earlier vehicles for water paints (alkali-solubilized casein, glues, dextrin, seaweed alginates, gum arabic, etc.) were largely supplanted by modified oils and synthetic resins, made water-dispersible yet water-resistant after drying. In late developments, vast employment was made of latices of polymers or co-polymers akin to the synthetic rubber group (styrene-butadiene, acrylonitrile, vinyl, acrylic esters, etc.), some of which impart strong resistance to staining and scrubbing. Such latices or emulsions, along with colloidal dispersions of the same types of resin in volatile thinners which do not dissolve them at ordinary temperatures (organosols) or in nonsolvent plasticizers (plastisols) came into wide use as transparent varnishes for coating paper, textiles and similar materials.

The varnish maker has striven constantly to make his varnishes flow more smoothly, dry faster, harder and tougher, and show better adherence, flexibility and durability so as to resist the strains of expansion and contraction of the wood, metal, plaster or other substrate, and the deteriorating effects of exposure to

heat, cold, ultraviolet light, moisture, alkali and other destructive factors. Natural resins and linseed oil permitted only limited attainment of these objectives, but with the ever-widening choice of synthetic polymers great improvement continued

Manufacture of Oil Varnish.—In the older form of the art which was almost universally practised up to about 1900, but which slowly lost importance after that time, the manufacture of an oil varnish began with hard fossil gums. These were natural resins exuded from ancient trees (some species of which are no longer extant) and made hard, brittle and lustrous by centuries of burial or exposure. They were dug, cleaned and assorted according to size, colour, hardness, etc , and shipped to the markets. The varnish maker crushed them to about ½ in. lumps and weighed the charge, of 50 lb. to 150 lb , into a copper or iron varnish pot or kettle, of a capacity of 40 gal to 150 gal A removable cover had a short central chimney for the escape of fumes, and holes near the edge for a metal stirrer and, sometimes, a thermometer. Smaller pots were lifted by hand, larger ones were rolled on low trucks, over a fire of coke, gas or fuel oil just below floor level. As the pot was intermittently heated to a final temperature of 330°–340° C , the gums, insoluble in oils before this "running" process, became pasty and eventually liquid, losing by volatilization and partial decomposition from 20% to 35% of their weight. The chemical nature of this change, and indeed the structure of the resin molecules themselves, had not been fully determined at mid-20th century, but the process was believed to involve depolymerization and partial conversion of complex organic acids from dicarboxylic to monocarboxylic types At a critical point as the melting process was completed, according to the judgment of the operator, addition of the preheated linseed (or other) oil, with vigorous stirring, was begun Heating was continued until solution was complete, as indicated by the clarity of a drop let fall from the stirrer upon a piece of glass The driers (consisting of oxides or salts of lead, manganese or cobalt, or combinations of them, in amounts sufficient to provide from about 0 03% to 0.6% of metal based on the oil) were next added and the mixture further boiled until these were dissolved as soluble soaps and the desired degree of bodying, or polymerization, attained. At a safe distance from the fire the pot was cooled somewhat, and the contents were thinned to a suitable consistency, by slow addition (with stirring) of turpentine or white spirit. The varnish was strained or filtered to remove dirt, pumped into storage tanks and allowed to age.

Varieties of oil varnish were differentiated as to oil length and as to use . Short-oil varnishes provided the extreme hardness needed for smooth rubbing with pumice stone, and sometimes further polishing with rottenstone or rouge, for fine cabinet and carriage work, among these were piano polishing varnish (5 gal. to 8 gal) and carriage rubbing and polishing varnish (6 gal. to 10 gal.). Japan gold size was an 8 gal. varnish for gilders' use and for binding coach colours, it dried in two hours or less In the medium-length group were floor, interior and gear varnishes (12 gal. to 20 gal). Body finishing (20 gal. to 30 gal.) and spar varnishes (25 gal. to 40 gal), requiring maximum flexibility, were in the long-oil group Flat varnishes for furniture and architectural work dried with a mat surface; baking or stoving varnishes (frequently containing no driers) were used over printed tinplate; insulating varnishes provided high resistance in electrical equipment.

Many other special types of oil varnishes were offered, with properties controlled by regulating the choice of resin or of oil, the degree of running, the subsequent cooking or the final blending of finished stocks.

A modification of varnish making technique was brought about by the introduction of tung (or China wood) oil, which began to reach Europe and America in important amounts about 1890–95. It bodies rapidly, forming a solid gel when heated alone at 285° C. for 6 to 12 mn.; it dries faster and harder than linseed and is more water-resistant, and it is improved rather than debased by being cooked with rosin (colophony), the resin of the pine tree, which had previously been regarded as a cheap adulterant for the fossil resins. Longer, paler, more flexible, more durable varnishes of equal or better drying speed and hardness began to replace the older types. They could be cooked in half the time or less, and, with rosin replacing fossil gum, premelting was unnecessary.

After the introduction of alkyd resins in the decade from 1925 to 1935, many firms began to make varnish in fixed closed chemical-processing kettles, of a capacity of 500 gal. and up. These are usually of stainless steel, heated either directly by gas, oil or electricity, or jacketed for heating by circulating heat-transfer fluid; they are provided with mechanical stirrers, pumps for applying pressure or vacuum, condensers for reflux or distillation, temperature-recording devices and piping for filling and emptying.

Oil is drawn by gravity from weighing tanks, heated and combined with synthetic resin which may be added in lump or liquid form, in many cases this resin is first manufactured in the same kettle. The progress of cooking is judged mainly from the temperature graph, and checked by taking samples at intervals which are tested for acidity, viscosity, curing time, etc When the batch is ready for thinning it flows by gravity to a large reducing tank that is placed on a scale and contains the proper amount of solvent. Here the varnish is thoroughly mixed by mechanical agitators, then filtered, aged and blended as before. With the change to synthetic resins, differentiation by oil-lengths became obsolete, but differentiation by uses is even more varied Finishes specifically designed for such individual uses as the various parts of television cabinets, aircraft, washing-machines, etc. are readily available

Manufacture of Spirit Varnishes and Lacquers.—Being mere solutions of resins, cellulose derivatives, proteins and the like in volatile solvents, spirit varnishes and lacquers are readily made by agitating the ingredients in large tanks with mechanical stirrers, or in rotating barrels or churns, until solution is complete (about 2 hrs. to 24 hrs.), rarely the resin is first melted, then thinned, or the mixture is refluxed. Filtering and aging complete the process. The cellulose esters by themselves lack adherence and flexibility; resins (nondrying alkyd or similar) and plasticizers are almost always added to overcome these deficiencies. French polish (*q.v.*), made by dissolving either bleached or amber shellac in methylated spirit, is one of the important types of spirit varnish. Crystal paper varnish, a water-white solution of 7 lb to 8 lb dammar gum in 1 gal. of turpentine, is used for varnishing wallpapers and delicate interior work; a similar varnish serves as vehicle in some interior white enamels.

Raw Materials for Varnishes.—In contrast to the limited number of materials available to the varnish maker prior to the 20th century, the considerable array at hand by the beginning of World War II was further broadened by intensive research to meet the needs of that conflict. Research in the fields of plastics, textiles and rubber brought out many new resins and elastomers which, with or without modification, were adapted for varnish use

Resins—(*See* also RESINS: *Synthetic Resins.*) Natural resins (other than shellac and rosin) in general originate in the Congo, Zanzibar and north coast districts of Africa, in New Zealand, the Netherlands East Indies, Malaya, the Philippine and nearby islands, and in South America. They are classified in various categories as spirit-soluble or (potentially) oil-soluble; as fossil (such as animi from Zanzibar, kauri from New Zealand, Congo and Boea copals, the latter from Netherlands Indies), semi-fossil (Batu and East India, of the dammar family) and "recent," or from living trees (dammar, sandarac, accroides, soft Manilas, elemi and mastic), and in degrees of hardness and insolubility, depending usually upon their age. Amber from the shores of the Baltic has long been too rare and high-priced for the varnish use it once had.

Ester gum, the earliest (about 1900) synthetic resin, was made by esterifying rosin (essentially abietic acid) with glycerine. By cooking it with tung oil in lengths of 40 gal to 50 gal., spar varnishes (so named because they were suitable for use on masts and spars of ships) could be made which dried hard overnight and withstood boiling water, or long immersion in cold water, without injury. Being compatible also with nitrocellulose, ester gum is largely used in lacquers. About 1910, coumarone-indene poly-

mers made from coal-tar light oil, and phenol-formaldehyde-rosin-glycerine (modified phenolic) condensates patented by Kurt Albert and F. N. Berend (albertols) were introduced These brought still faster drying rates, embodied in the so-called four-hour varnishes, but they tended to discolour on exposure In 1928 came the first "100% phenolic" oil-soluble resin, a thermoplastic condensate of paraphenyl phenol with formaldehyde, followed later by a number of resins of better colour retention made from alkyl-substituted phenols. With these resins, 20-gal varnishes were found more durable than longer ones, reversing the usual rule, they showed remarkable resistance to water and chemicals. Similar in general properties to the modified phenolics are the maleic ester gums or maleic alkyds (glycerides of an adduct of rosin with maleic or fumaric acid). They are pale, hard, colour-retentive, and find use in lacquers as well as oil varnishes New ways were found of improving rosin by hydrogenation or dehydrogenation, polymerization or esterification with pentaerythritol, sorbitol and other polyhydric alcohols. Other hard resins for oil varnishes, such as those made by chlorinating natural or synthetic rubber, paraffin wax or diphenyl; by condensing or "cyclizing" rubber; by polymerizing terpenes; by combining olefines with diolefines, or by special treatment of petroleum residues, have their special uses such as in finishes for concrete, aluminum bronze paints, etc.

One of the most important groups of synthetic resins is the alkyd or glyptal, basically the chemical combination of a polyhydric alcohol (*e.g.*, glycerine, glycol, pentaerythritol) with a polybasic acid (such as phthalic, maleic or sebacic) and a fatty acid (or mixture of acids such as those of linseed, soybean or castor oils). The alkyd resins can replace, in part or in whole, the blend of natural fossil or other hard gum with drying oil of the earlier varnish type. They can be modified by changing each of the three types of ingredient and their relative proportions over a wide range of properties, from hard and brittle to extremely flexible, tough and durable. Those made with nondrying fatty acids are much used in lacquers and particularly in stoving finishes; in these last, a very great advance resulted from the introduction of butylated amine-formaldehyde resins (urea or melamine), as hardeners: increased hardness and toughness, improved colour-retention at high temperatures, and reduction in baking time to a few minutes In the late 1940s, epoxy resins, made by polymerizing the reaction product of bis-phenol with epichlorhydrin, provided additional hardness, adherence, flexibility and alkali resistance. This reaction product, itself a resin, has residual hydroxyl groups and may be combined with fatty acids, amines or polyamides to enhance these properties.

New insulating varnishes developed during World War II enabled motors to deliver two or three times their rated horsepower by running much hotter without burning out. These were based on silicone resins in which silicon partially replaces carbon in a complex molecular structure. From these resins were later developed varnishes which, although they are expensive and require high stoving heats, have such good resistance to high temperatures and to weathering that their use on such things as heater parts, smokestacks and outdoor signs gradually increased. Copolymers of silicone resins with alkyds have intermediate properties.

For spirit varnishes of the alcohol type, shellac and the other forms of lac, and the "recent" natural resins (*i.e.*, sandarac, Melengket and Loba manilas, elemi and accroides) are augmented by rosin-fumaric acid and terpene-maleic anhydride adducts and by other modifications of rosin, as well as by the protein from maize and the polyvinyl formal resins (including acetals and butyrals) Polyamide resins (compounds of glycols with the amides of dimerized fatty acids), allyl starch and allyl sucrose and modifications of nylon were developments of the 1940–50 decade. In the hydrocarbon-soluble group are the polymers of styrene and methyl styrene, polyvinyl acetate, one or two of the acrylic-ester polymers, and many of the above-mentioned oil-soluble materials. Resins requiring ketone or ester-type solvents are the polymers and copolymers of vinyl chloride, vinylidene chloride and of most of the esters of acrylic and methacrylic acids.

Of the cellulose derivatives, nitrocellulose is most common; the less flammable but more expensive acetate, propionate and acetate-butyrate meet some special requirements. The ethers, ethyl cellulose and to a very limited extent benzyl cellulose, are of increasing interest (Methyl cellulose, hydroxyethyl cellulose, and sodium carboxymethyl cellulose are water soluble and are used as grease resistant clear varnishes or as protective colloids in emulsion finishes)

Plasticizers.—To impart necessary flexibility, plasticizers must almost always be added, not only to cellulose lacquers but to those based on vinyl resins, etc. They include (1) oils, such as raw or blown castor, blown linseed or soybean; (2) chemical solvents of extremely low volatility (esters, ketones, aromatic hydrocarbons, etc). tricresyl phosphate, dibutyl, diamyl or dioctyl phthalate and some of the sebacates are among the best-known of the scores of compounds available; and (3) certain resins of the thermoplastic or polyester type

Drying Oils.—Linseed oil, expressed from flaxseed (*Linum usitatissimum*) grown in Canada, the United States, India, Argentina, U.S.S.R and other parts of Europe, is the mainstay of the varnish industry, but until supplies from China were cut off during World War II and in some later years, tung oil (from the seeds of *Aleurites fordii* or *A cordata*) was gaining rapidly, as was also perilla oil (*P. ocimoides*) of later introduction from Manchuria. Tung orchards in the U.S. and some South American countries, planted from about 1925, did not produce enough oil to meet world demands. These three vegetable oils, with the fish oils (menhaden, sardine, pilchard) and the semidrying oil from soybeans, made up 98% of the total oils used by the varnish industry in 1935. Oiticica oil, from *Licania rigda* of Brazil, an oil somewhat similar to tung, entered world commerce in the 1930s, and with dehydrated castor oil, which simultaneously began to be prominent, largely filled the gap in tung oil supplies. Sunflower, safflower, poppyseed, maize and many other oils have been used in limited amounts. Synthetic drying oils are mentioned below

For varnish making the natural oils (other than tung and oiticica) are refined by heating with small amounts of lye or of sulphuric acid, which precipitate the traces of chlorophyll and mucilaginous matter (chiefly phosphatides) remaining in them when pressed from the seed; otherwise a discolouring "break" or cloud forms during the cooking of the varnish. Sometimes the oils are prebodied, either by themselves or with driers, before incorporation into varnishes, or they may be blown with air, introduced through perforated pipes, at temperatures of 60°–120° C., causing partial oxidation and thickening Boiled oil is usually made by simply dissolving small amounts of soluble driers (the resinates, linoleates, naphthenates, etc , of lead, manganese or cobalt) in linseed oil at moderate temperature.

Thinners or Solvents.—Turpentine is the essential oil (largely pinene, $C_{10}H_{16}$, and its isomers and polymers) distilled from "gum thus," the sap obtained by tapping various species of pinus (*P. palustris*, U.S.; *P. maritima*, France; *P. sylvestris*, U.S.S.R.), or steam-distilled from chipped wood from the stumps, or (from about 1945) recovered as a by-product in making wood pulp for paper. It has excellent solvent properties for resins and oils, but by 1930 it had become too scarce and expensive for most varnish purposes. Distillates from petroleum in approximately the same boiling range (155°–175° C.), called white spirit or mineral spirits, had almost entirely replaced it. These distillates, consisting mostly of aliphatic hydrocarbons, are not as powerful solvents for some of the highly polymerized synthetic resins or oxidized oils; upon strong dilution with these thinners, cloudiness or precipitation may sometimes result. Toluene, xylene and high-boiling aromatic hydrocarbons derived either from coal tar or petroleum are partially or wholly employed for such difficultly-soluble varnish bases.

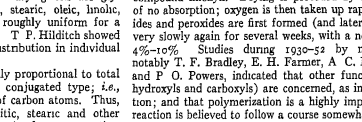
In spirit varnishes, single or blended solvents are chosen (to fit the solubility of the particular resin) from among the alcohols, hydrocarbons, ketones, chlorinated hydrocarbons, esters, etc. For cellulose lacquers, the main solvents are esters (ethyl, butyl and amyl acetates and propionates, and many others); ketones (acetone, methylethyl ketone, methylisobutyl ketone, etc.); ether alcohols (ethoxy- and butoxyethanol, etc.) and their acetates,

and the nitroparaffins Alcohols, not in themselves solvents for cellulose nitrate or acetate, increase the solvent power of esters.

A considerable proportion of toluene or other hydrocarbon diluent (a nonsolvent for the cellulose compound) is generally used, partly to reduce cost and partly to assist in dissolving resins in the composition; thus, a common blend is three parts ethyl or butyl acetate, one part of the corresponding alcohol, six parts toluene Care must be taken in compounding such solvents to avoid "blushing" or whitening of the film, caused either by too much diluent, by slower evaporation of diluents than of solvents, or by condensation and absorption of moisture from humid air because of the cooling effect of too-rapid evaporation.

The increasing use of spraying (either cold or hot), dipping, tumbling, roller-coating, etc., in place of brushing, especially in the application of industrial finishes, requires a choice of thinners whose rate of evaporation is suitable for each particular method.

Other Raw Materials.—As catalysts for the oxidation-polymerization reaction, soluble salts or soaps of metals with two valence levels (especially cobalt, manganese and lead) are effective, lead tends to dry the film throughout, the other two are so-called top driers. Other elements, such as iron, vanadium, zinc (for hardening) and calcium (to minimize wrinkling), are sometimes employed. Waxes, or silica of impalpable fineness produce flat or mat finishes without reducing transparency. Modern varnishes may include minute amounts of surface-active agents to aid in application, in incorporation of pigments and (with latices) to stabilize the emulsions; antioxidants, to reduce the tendency to form a skin over the liquid surface in a partly filled container, and other additives for special purposes.



Chemistry of Drying Oils.—Natural drying oils are glycerides of various fatty acids—palmitic, stearic, oleic, linoleic, linolenic, etc.—in proportions which are roughly uniform for a given oil, but differ from one oil to another T P. Hilditch showed that the acids followed the law of even distribution in individual molecules

Speed and hardness of drying are roughly proportional to total unsaturation, especially where this is of conjugated type; *i.e.*, with double bonds joining adjacent pairs of carbon atoms. Thus, linseed oil contains about 8% of palmitic, stearic and other saturated acids which contribute nothing to its drying properties, 5% of oleic with one double bond (in 9-position, *i.e.*, joining the 9th and 10th carbon atoms from the carboxyl end), 48% of linolic with two double bonds (9, 12) and 34% of linolenic with three double bonds (9, 12, 15). Wilt resistant strains of flax yield oils with lower percentages of unsaturated acids, the drying quality being sacrificed to some extent in order to assure a sufficient crop Perilla oil, with 42% each of linolic and linolenic acid, dries and bodies even faster than linseed Some of the fish oils contain acids with 4 or 5 double bonds, but this is offset by higher percentages of saturated acids. The very low linolenic acid content of most semidrying oils (soybean, poppyseed, maize, etc.) accounts for slower drying and softer films, but less discoloration on aging (especially in the dark).

Tung oil contains about 73% of elaeostearic acid, with three conjugated double bonds (9,11, 13). This structure is responsible for the rapid polymerization of the oil either when heated alone to above 250° C, or in films. The surface layer of such films (of the raw or blown oil) expands on drying to form wrinkles or "crystals" in a frosted effect, which may be made use of in specialty finishes, although the oil is usually "gasproofed" by heating below 250° C., either alone or with rosin or other resins. Licanic acid, chief component of oiticica oil, differs from elaeostearic only in having a keto group in the 4-position; thus oil bodies and dries a little slower than tung, but shows a similar frosting tendency.

The observation that conjugated unsaturation confers not only faster bodying and drying, but also better water resistance and durability upon oils led to attempts to produce it in slower or nondrying oils. Johann Scheiber and Hanns Ufer in Germany found that from ricinoleic acid (12-hydroxy-9-octadecenoic acid), a chief component of castor oil, a molecule of water could be removed by heating with catalysts to about 275° C., and an additional double bond thus formed. A large amount of castor oil has, since about 1938, been dehydrated by such treatment, and a "frosting" drying oil produced, by most processes in use, about 17%–26% of the oil takes the conjugated (9, 11) form, while the balance goes to the unconjugated (9, 12) form with a methylene group between the double bonds. Later, it was found that by special catalytic treatments linseed, soybean and other nonconjugated oils could be converted up to about 30% to the conjugated form, and their drying speed and hardness improved; indeed there is strong evidence that the ordinary heat-bodying of these oils produces a small amount of conjugation by intramolecular rearrangement. Castor-oil dehydration opened the door to much experimentation and progress in oil technology previously limited to refining and bodying processes; nature's products are no longer accepted as the last word. Among the methods of improvement, applied chiefly to linseed, soybean and fish oils with or without preliminary polymerization to a viscosity of about 30 poises, are segregation into portions of greater and less unsaturation by differential solubility in acetone, furfural or other solvents; fractional distillation of the fatty acids, the more unsaturated of which are then re-esterified with glycerine, pentaerythritol, sorbitol or other polyhydric alcohol; treatment with maleic anhydride, which by the Diels-Alder reaction forms an adduct at the double bonds, and copolymerization with cyclopentadiene, styrene, methacrylic acid and other unsaturated compounds.

The mechanism of drying of linseed and other drying oils was still imperfectly understood at mid-20th century. Drying was formerly considered to be caused entirely by the absorption of oxygen at double bonds of the acid chains to form a complex solid compound linoxyn. Drying is preceded by an induction period of no absorption; oxygen is then taken up rapidly as hydroperoxides and peroxides are first formed (and later decomposed), then very slowly again for several weeks, with a net gain in weight of 4%–10%. Studies during 1930–52 by many investigators, notably T. F. Bradley, E. H. Farmer, A C. Elm, J. L. Overholt and P O. Powers, indicated that other functional groups (*e.g.*, hydroxyls and carboxyls) are concerned, as in alkyd resin formation; and that polymerization is a highly important factor. The reaction is believed to follow a course somewhat as follows. During the induction period the tocopherols or other natural antioxidants present in the oil are oxidized; then oxygen adds (to form peroxides or hydroperoxides), either at the double bonds of the dienoic or trienoic acids of the glyceride or at the active methylene group between them. Dehydration of the peroxides appears to account for formation of carbonyl groups and evolution of water; some reduction also probably occurs Shifts of double bonds to conjugated positions may immediately follow, leading to cross-linking of the acid chains in the same, or more often in different, molecules by a Diels-Alder mechanism to form a cyclohexenic adduct:

Some linking or "vulcanization" by oxygen probably also occurs. Thus dimers and trimers of the glyceride molecules are formed; the viscosity increases rapidly, ending in gelation and the formation of a dry film. The conjugation already present in tung, oiticica and dehydrated castor oils explains their faster reaction.

In blowing oils, much the same sequence of transformation is set in motion; in thermal polymerization, conjugation is a slower process but it does take place and the bodying is caused by polymerization alone.

Resins containing unsaturated fatty acids (*e.g.*, alkyds) undoubtedly owe their drying properties largely to this same mechanism; it contributes an added functionality to that which, as shown by W. H. Carothers and R. H. Kienle, is involved in the original formation of resins by polymerization or condensation of monomers.

Varnish films deteriorate or fail in service largely through at-

tack at weak molecular linkages such as those of the ester type. Durability increases as these are replaced by stronger ones like those of the ether or the carbon-to-carbon type, as in many of the newer synthetic varnishes. (*See also* OILS, FATS AND WAXES.)

VARNUM, JAMES MITCHELL (1748–1789), U.S. Revolutionary soldier and public official, was born at Dracut, Mass., on Dec 17, 1748 After attending Harvard college, he studied at Rhode Island college (later Brown university, Providence, R.I), where he was graduated in 1769. Two years later, after reading law in the office of the attorney general of Rhode Island, he was admitted to the bar and began to practise law. He soon became known for his eloquence.

After serving as a colonel and later as a brigadier general in charge of Rhode Island troops, he was appointed a brigadier general in the Continental army in 1777. He held various commands, winning commendations though he was unsuccessful in defending Forts Mercer and Mifflin on the Delaware river During the winter of 1778 he was at Valley Forge with George Washington, and he later served in the campaign in Rhode Island

Varnum resigned from the Continental army in March 1779, but he served as major general of the Rhode Island militia from 1779 until 1788.

He was a member of the Continental congress at various times during the period from 1780 to 1787.

Varnum was appointed U S. judge in the Northwest territory, for which he helped write a legal code. He died at Marietta, O., on Jan 10, 1789.

James Varnum's brother, JOSEPH BRADLEY VARNUM (1750/51–1821), who served as an officer in the Massachusetts militia, became speaker of the U S. house of representatives and was a U.S. senator from Massachusetts from 1811 until 1817 He was a strong advocate of the War of 1812. Before serving in the federal congress, Joseph Varnum had been a member of the Massachusetts legislature, to which he returned as a state senator

See J M. Varnum, *The Varnums of Dracut in Mass.* (1907).

VARRO, MARCUS TERENTIUS (116–27 B C), Roman antiquarian and man of letters, was born at Reate. He studied at Rome under L. Aelius Stilo, the first Roman grammarian, and at Athens under Antiochus of Ascalon. In politics he espoused the side of Pompey. He disapproved, apparently, of the first triumvirate (that of Pompey, Caesar and Crassus, 60 B.C.), which he ridiculed in a book called *The Three-headed* (Τρικάρανος: *cf.* Appian *Civil War*, ii.9, καί τις αὐτῶν τήνδε τὴν συμφοροσύνην συγγραφεὺς, Οὐάρρων ἐνὶ βιβλίῳ περιλαβὼν ἐπέγραψε Τρικάρανον). Under Pompey he saw considerable military service and was engaged in several operations during the Civil War Before the battle of Pharsalia he went to Epirus, and along with Cicero and Cato, he awaited at Dyrrachium the issue of the conflict. His personal relations with Caesar were friendly, and when, after the defeat and Pompey, Caesar secured the restoration of some of Varro's property, which had been seized by Mark Antony, Varro showed his gratitude by dedicating to him the second part of his *Antiquitates*. He also assisted Caesar in collecting Greek and Latin literature for the great public library which he contemplated. On the formation of the second triumvirate (that of Octavianus, Antony and Lepidus 43 B.C.), Varro was proscribed, but through the good offices of Q. Fufius Calenus he was able to come to terms with the triumvirs and the remaining years of his long life were spent in study and writing.

Volume of Writings.—Varro was not only the most learned of Romans, but also the most voluminous of Roman writers (*homo πολυγραφώταros* Cic., *Ad Att*, xiii.12). Aulus Gellius, iii., 10 17 quotes Varro as saying that "he had now entered on the 12th hebdomad of years (*i.e.*, was between 78 and 84), and up to that day had written 70 hebdomads (*i e*, 490) of books, of which some considerable number had not appeared, his libraries having been plundered when he was proscribed." Jerome's catalogue of his works is preserved in a mutilated form in Rufinus, pref. to translation of the homilies of Origen. From this and other evidence Ritschl puts the number of his separate literary works at 74 and the number of "books"—counting, for example, the 150 *Menippean Satires* as 150 "books"—at about 620.

Conspectus of Writings.—His work, which survives only in fragments, with the exception of the *De Lingua Latina*, of which six books are extant, and the *Rerum Rusticarum libri tres* which is extant almost entirely, may be considered under various heads:

1. *Saturae Menippeae* in 150 books These were medleys in prose and verse in the style of Menippus, a Cynic philosopher of the first half of the 3rd century B.C. (Aul. Gell., ii. 18.6). The titles, often Greek, of the individual Satires are of the most varied kind—sometimes personal names of gods or men; sometimes proverbs, Greek or Latin, *e.g*, *Nescis quid vesper serus vehat* (You know not what evening may bring forth), Δὶς παῖδες οἱ γέροντες (Old men are in their second childhood), Γνῶθι σεαυτόν (Know thyself). And the range of subject is no less wide and varied—eating and drinking (*Est modus matulae, περὶ μέθης, περὶ ἐδεσμάτων, ὀψοκίων*), literature (*Parmeno*), philosophy (*περὶτκλους, περὶ αἱρέσεων, armorum iudicium*), politics (the Τρικάρανος mentioned above), praise of the good old times (*Sexagesis*, Γεροντο-διδάσκαλος, Bimarcus)—in a word, Varro might have said with Juvenal (i. 85): *quidquid agunt homines, votum timor ira voluptas gaudia discursus, nostri est farrago libelli.* So far as can be judged from the fragments the Menippean Satires had no great merit either of style or content, but the frequency with which they are quoted in later writers suggests that they were the most generally popular of Varro's writings.

2. *Logistoricon libri LXXVI.*, treatises on philosophical, historical and other subjects, generally with a chronological basis, *e g*, *Catus aut de liberis educandis* (Aul. Gell , iv.19, *cf* xx.11); *Orestes vel de insania* (Aul Gell., xiii 4); *Pius aut de pace* (Aul Gell, xvii.18); *Sisenna vel de historia* (Aul Gell., xvi 9).

3 *Imagines* in 15 books. This consisted of 700 biographies of famous Greeks and Romans, each biography being accompanied by a portrait of the subject and an explanatory metrical *elogium*. This was probably the first Latin illustrated book, but Cratenas, the medical attendant of Mithridates VI. (120–63 B.C.) had shown the way to an illustrated book (Ῥιζοτομικὸν) on plants. The number of biographies, 700, is explained by Varro's curious affection for the number 7 (*hebdomas*) *cf.* Aul Gell., iii. 10. 1 "M. Varro in the first of the books entitled *Hebdomades* or *De Imaginibus* says that the virtues and powers of the number 7, which the Greeks call ἑβδομάς are many and various": *cf.* iii.11.3, *M. Varro in primo de Imaginibus, uter* (Homer or Hesiod) *prior sit natus, parum constare dicit;* ibid. 6. M. Varro in the first book, *de Imaginibus*, placed them under the portrait of Homer this epigram: *Capella Homeri candida haec tumulum indicat Quod hac Ietae mortuo faciunt sacra* (This shining she-goat indicates the tomb of Homer, because it is with a she-goat that the Ietae sacrifice to the dead).

4. On literature and the history of literature he wrote a series of treatises, *e.g., De poematis, De compositione saturarum, De Poetis* (Aul Gell., i 24,3; xvii 21, 43 and 45), *De originibus scaenicis, De comoedis Plautinis* (Aul Gell., iii 3 9 seq), *Quaestionum Plautinarum libri V.* In this connection it is to be noted that Varro established the canon of the genuine plays of Plautus, the 21 so-called *Fabulae Varronianae, i e.*, the 21 plays now extant (the *Vidularia* only partially).

5. *Antiquitatum rerum humanarum et divinarum libri XLI.* Of this work the first 25 books dealt with *res humanae*, the second part in 16 books, dedicated to Caesar, dealt with the gods. For the first part, *cf.* Aul Gell., i 16, i.25, iii.2, v 4, xi.1, xii.12, xiii 13, xiii 17, xvii 3; for the second part *cf.* Aul. Gell., i.18, iii.16, x.15, xv.30, xviii 12. Other works in this sphere written by Varro were *De gente populi Romani libri IV, De vita populi Romani, De familiis Troianis, Tribuum liber, Rerum urbanarum libri III, Aetia* (so called after the Αἴτια of Callimachus).

6. Historical works: *De Pompeio libri III., Annalium libri III., De sua vita, Legationum libri III.*

7. Encyclopaedic works: *Disciplinarum libri IX.* (*cf.* Aul. Gell.,

i.20, x.1, xviii 15), dealing with the liberal arts, grammar, rhetoric, music, medicine, etc., *De forma philosophiae libri III.*

8. Legal work: *De jure civili libri XV.*

9. Geographical works: *De ora maritima, De aestuariis, Ephemeris nivalis.*

10. Grammatical works: *De lingua Latina libri XXV.*, of which books 2–4 were dedicated to P. Septimius, the rest to Cicero; *cf* Aul. Gell., ii 25, vi 11, x.21, xvi 8 Bks. 5–10 are extant in a somewhat mutilated condition. The work was divided into three parts, the first dealing with the etymology of Latin words, the second with inflexion, the third with syntax. Other works in this sphere by Varro were *De sermone Latino ad Marcellum libri V.* (*cf.* Aul. Gell., xi 6, xii 10, xvi.12, xviii 12); *De similitudine verborum; De utilitate sermonis; περὶ χαρακτήρων; De antiquitate litterarum; De origine linguae Latinae.*

11. *Epistolicae Quaestiones* (Aul Gell, vi.10, xiv.7, xiv 8) dealing with a variety of subjects

12. *Rerum rusticarum libri III.*, written when Varro was in his 80th year. (*Cf.* the opening words, "If I had leisure, Fundania, I would have written for you more conveniently what I will now set forth as best I can, considering that I must make haste, since, as the saying goes, if man is a bubble, still more so is an old man. My 80th year warns me that I must collect my baggage before I depart from life.") This work (for which *cf.* Aul. Gell, ii. 20) is extant practically entire.

Estimate of Contemporaries.—It is a very remarkable fact that Livy nowhere in his extant work alludes to Varro, or gives any evidence of acquaintance with his writings. But the reputation which he enjoyed, both in his own day and in later times, is abundantly testified: Cic., *Acad post.*, i.3. "You have revealed to us the age of our fatherland, its chronology, the laws of its religion and priesthoods, the plan of our home and foreign administration, the position of our territories and districts, the titles and descriptions of all things Divine and human, with the duties and principles attaching to them, and you have shed a vast amount of light on our poets and on Latin literature in general and on the Latin vocabulary, while you have yourself composed picturesque and choice poems in almost every metre, and in many passages have touched upon philosophy, so far as to arouse interest, but not sufficiently for full treatment."

Bibliography.—*De lingua Latina*, edit. C. D. Muller, L. Spengel re-edited by his son (1885); *Res Rusticae*, edit. Keil (Leipzig, 1884). VARTHEMA (Barthema, Vertomannus, etc.), **LUDOVICO DI**, of Bologna (*fl.* 1502–1510), Italian traveller and writer, left Europe near the end of 1502; early in 1503 he reached Alexandria and ascended the Nile to Cairo. From Egypt he sailed to Beirut and thence travelled to Tripoli, Aleppo and Damascus, where he managed to get himself enrolled, under the name of Yunas (Jonah), in the Mamelukе garrison—doubtless after adopting Islam. From Damascus he made the pilgrimage to Mecca and Medina as one of the Mamelukе escort of the Hajj caravan (April–June 1503); he describes the sacred cities of Islam and the chief pilgrim sites and ceremonies with remarkable accuracy, almost all his details being confirmed by later writers. With the view of reaching India, he embarked at Jidda and sailed down the Red sea and through the Straits of Bab-el-Mandeb to Aden, where he was arrested and imprisoned as a Christian spy. He gained his liberty—after imprisonment both at Aden and Radaa—through the partiality of one of the sultanas of Yemen, made an extensive tour in south-west Arabia (visiting Sana, etc.), and took ship at Aden for the Persian Gulf and India. On the way he touched at Zaila and Berbera in Somaliland; he then (early in 1504?) ran across to the Indian port of Diu in Gujarat, afterwards famous as a Portuguese fortress. From Diu he sailed up the Gulf of Cambay to Gogo, and thence turning back towards the Persian Gulf made Julfar (just within the entrance of the gulf), Muscat and Ormuz. From Ormuz he seems to have journeyed across Persia to Herat, returning thence south-west to Shiraz, where he entered into partnership with a Persian merchant, who accompanied him during nearly all his travels in South Asia.

After an unsuccessful attempt to reach Samarkand, the two returned to Shiraz, came down to Ormuz, and took ship for India. From the mouth of the Indus Varthema coasted down the whole west coast of India, touching at Cambay and Chaul; at Goa, whence he made an excursion inland to Bijapur, at Cannanore, from which he again struck into the interior to visit Vijayanagar on the Tungabudra; and Calicut (1505?), where he stopped to describe the society, customs and institutions of Malabar, as well as the topography and trade of the city. Passing on by the "backwater of Cochin," and calling at Kulam (Quilon), he rounded Cape Comorin, and passed over to Ceylon (1506?) Though his stay here was brief (at Colombo?), he learnt a good deal about the island, from which he sailed to Pulicat, slightly north of Madras, then subject to Vijayanagar. Thence he crossed over to Tenasserim in the Malay peninsula, to Banghella, perhaps near Chittagong, at the head of the Bay of Bengal, and to Pegu, in the company of his Persian friend and of two Chinese Christians (Nestorians?) whom he met at Banghella. After some successful trading with the king of Pegu, Varthema and his party sailed on to Malacca, crossed over to Pider (Pedir) in Sumatra, and thence proceeded to Bandan (Banda).

From the Moluccas he returned westward, touched at Borneo, and there chartered a vessel for Java, the "largest of islands," as his Christian companions reckoned it. He notes the use of compass and chart by the native captain on the transit from Borneo to Java, and preserves a curious, more than half-mythical, reference to supposed Far Southern lands. From Java he crossed over to Malacca, where he and his Persian ally parted from the Chinese Christians; from Malacca he returned to the Coromandel coast.

Varthema was now anxious to resume Christianity and return to Europe; after some time he succeeded in deserting to the Portuguese garrison at Cannanore (early in 1506?). He fought for the Portuguese in various engagements, and was knighted by the viceroy Francisco d'Almeida, the navigator Tristan da Cunha being his "sponsor." For a year and a half he acted as Portuguese factor at Cochin, and in 1507 (?) he finally left India for Europe by the Cape route. Sailing from Cannanore, Varthema apparently struck Africa about Malindi, and (probably) coasting by Mombasa and Kilwa arrived at Mozambique, where he notices the Portuguese fortress then building, and describes the negroes of the mainland. He finally arrived safely in Lisbon.

Varthema's work (*Itinerario de Ludovico de Varthema Bolognese . . .*) was first published in Italian at Rome in 1510 (*ad instãta de Ludouico de Henricas da Corneto Viterbino*). Other Italian editions appeared at Rome, 1517, at Venice, 1518, 1535, 1563, etc. The first English translation was of 1576–77 (in Richard Eden's *History of Travayle*); an extract from Varthema was inserted in Samuel Purchas's *Pilgrimage* (1625–26); and in 1863 appeared the Hakluyt Society edition by J. W. Jones and G. P. Badger (*Travels of Ludovico di Varthema*). (C. R. B.)

VARUNA, in Vedic Hindu mythology the associate of Mitra, whose individuality faded while Varuna's gained ground by a process still obscure. In contrast to Indra, the war-god, who was supreme, Varuna has no myths related of him. But in post-Vedic myth Varuna sinks to the position of a departmental god—of the waters—being replaced by Prajāpati as the supreme.

VASA (Vaasa or Nikolaistad), a seaport of Finland in 63° 6′ N., 21° 36′ E., on the east coast of the Gulf of Bothnia. Pop. (1940) 34,083. It is the chief town of a department of the same name. Vessels enter from the sea at Rönnskär, 26 mi. distant, and the channel is safe for vessels drawing 22 feet. The exports are timber, tar, etc., and the imports coal and salt, and there is a ship-repairing yard. The town was founded in 1606, and after its destruction by fire in 1852 was rebuilt nearer the shore.

VASARI, GIORGIO (1511–1574), Italian painter and architect, whose main distinction, however, rests on his valuable history of Italian art, was born at Arezzo on July 30, 1511. At a very early age he became a pupil of Guglielmo da Marcilla, a very skilful painter of stained glass. At the age of thirteen he went to Florence, where he studied under Michelangelo, Andrea

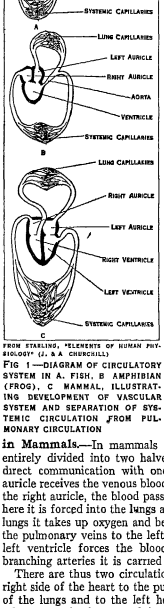
del Sarto and Baccio Bandinelli aided by the patronage of the Medici princes. In 1531 he visited Rome in the suite of Cardinal Ippolito de Medici and studied the works of Raphael and others of his school The paintings of Vasari were much admired. Vasari's principal works are at Florence, Rome, Naples, Arezzo, Bologna, Bosco (near Alexandria), Lucca, Monte Sansovino, Pisa, Perugia, Pistoja. Many of his pictures still exist, the most important being the wall and ceiling paintings in the great hall of the Palazzo Vecchio in Florence, and his frescoes on the cupola of the cathedral He died at Florence on June 27, 1574, and was buried in the chapel of S Giorgio in the Pieve of Arezzo

Personally Vasari was a man of upright character, always ready to appreciate the works of others: in spite of the very different taste of his time, he expresses a warm admiration of the works of Giotto, which is very remarkable. As an art historian of his country he must always occupy the highest rank. His great work *Delle Vite de' più eccellenti pittori, scultori, ed architettori*, was first published in 1550, and afterwards partly rewritten and enlarged in 1568 It was dedicated to Cosimo de' Medici, and was printed at Florence by the Giunti; it is a small quarto illustrated with many woodcut portraits. This *editio princeps* of the complete work is usually bound in three volumes, and also contains a very valuable treatise on the technical methods employed in all branches of the arts, entitled *Le Tre Arti del disegno, cioè architettura, pittura, e scoltura*. His biographies are written in a very pleasant style, interspersed with amusing stories With a few exceptions Vasari's judgment is acute and unbiased. The work in any case remains a classic, however it may be supplemented by the more critical research of modern days.

Vasari gives his own biography at the end of his *Vite*, and adds further details about himself and his family in his lives of Lazzaro Vasari and Francesco Salviati. The first edition of his *Vite* was issued by the Torrentino Press (1550). The best edition is that published at Florence by Milanesi (1878–1882), which embodies the valuable notes in the earlier edition by Le Monnier (1846). The *Lives* has been translated into French, German and English.

See Sir D Colnaghi, *Dict. of Florentine Artists* (1928); on his literary works *see* W. Kallab, *Vasaristudien* (Vienna, 1908); and J. Schlosser, *Die Kunstliteratur* (Vienna, 1924), which also contains an account of his life.

VASCO DA GAMA: *see* GAMA, VASCO DA.



VASCULAR SYSTEM. The unicellular organism receives all the supplies necessary for its growth and maintenance directly from its environment, either by diffusion of substances held in solution, or by direct intake of foodstuffs, which undergo chemical disintegration in vacuoles containing liquid into which the necessary enzymes are secreted. In the multicellular organism, such direct intake of foodstuffs by diffusion by every individual cell is impossible, for only the outer layer of cells is in contact with the environment, and this layer is usually protected by some form of membrane which is impermeable to water and food substances.

The vascular system has been developed to convey nutrient materials, etc, to the various parts of the organism, and the blood serves as intermediary between the environment and the organs of the body. This function can be fulfilled only if the blood is in continuous circulation, carrying nutrient materials and oxygen to the tissues, and conveying the waste products of metabolism from the tissues to the places where they are excreted. The heart is the organ which provides the necessary energy for this circulation, and the blood vessels are the channels which convey the blood to and from the tissues.

In the case of most invertebrate animals, the blood or analogous fluid is not all enclosed in blood vessels, and the various tissues lie freely in the fluid; which is kept in constant motion. In the higher animals, however, the blood is entirely enclosed in a system of tubes, and the nutrient substances, etc., are brought into contact with the cells only after their diffusion through the thin walls of the finest blood vessels. By the force of the cardiac contraction, the blood is driven through the tissues by way of thick-walled tubes, the arteries, and back to the heart by a system of thinner-walled vessels, the veins. In the tissues, the blood passes through a fine meshwork of capillaries, the walls of which consist of a single layer of delicate cells, which allow a free interchange of material to take place between the blood within and the tissue fluids outside the vessel.

THE HEART

In fishes (fig. 1, A) the heart consists of one auricle and one ventricle The blood is received from the great veins into the auricle. By the contraction of the auricle the blood is forced into the ventricle and this, when it contracts, sends the blood on to the bulbus arteriosus The blood passes through the branchial arteries into the gills, where it takes up oxygen, and then flows on into the aorta, by which it is distributed to the organs of the body. From the capillaries of these organs the blood is collected by the veins and is carried once more back to the auricle. The fish heart is thus entirely on the venous side of the vascular system

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG 1.—DIAGRAM OF CIRCULATORY SYSTEM IN A, FISH. B AMPHIBIAN (FROG). C MAMMAL, ILLUSTRATING DEVELOPMENT OF VASCULAR SYSTEM AND SEPARATION OF SYSTEMIC CIRCULATION FROM PULMONARY CIRCULATION

In amphibia, such as the frog, the heart consists of two auricles and one ventricle (fig 1, B) The right auricle receives venous blood from the body and forces it by its contraction into the ventricle From the ventricle the blood passes into the aorta, whence it is carried partly by the pulmonary artery to the lungs, partly by other arteries to the different organs of the body. The blood, which has passed through the lungs and been arterialised, flows through the pulmonary veins to the left auricle, whence it passes into the ventricle and mixes with the venous blood which is arriving from the right auricle. The pulmonary circulation is thus merely a branch of the general or systemic circulation The bulbus aortae in the frog is divided into two parts by means of a spiral valve, by which a partial separation of the blood coming from the right and left auricles is effected, and the venous blood from the right auricle is directed especially into the pulmonary artery.

Course of the Circulation in Mammals.—In mammals and birds, the heart has become entirely divided into two halves, right and left, which have no direct communication with one another (fig. 1, C). The right auricle receives the venous blood from all parts of the body From the right auricle, the blood passes to the right ventricle, and from here it is forced into the lungs along the pulmonary artery In the lungs it takes up oxygen and becomes arterial, and is returned by the pulmonary veins to the left auricle and to the ventricle. The left ventricle forces the blood into the aorta, whence by the branching arteries it is carried to all parts of the body.

There are thus two circulations—the one *pulmonary*, from the right side of the heart to the pulmonary artery and the capillaries of the lungs and to the left heart by the pulmonary veins; the other *systemic*, from the left side of the heart, by the aorta, to the arteries and capillaries of the body tissues and organs, from which by the veins to the right side of the heart. A schematic representation of the circulatory system is given in fig. 2 The muscular walls of the right ventricle are much thinner than those of the left ventricle. This is so because the energy required of the left ventricle must exceed that of the right ventricle, as resistance in the systemic circuit exceeds that in the pulmonary circuit.

The heart becomes filled with venous blood during its relaxation or *diastole*, and forces the blood into the arteries during its contraction or *systole*. The large arteries are of less capacity than the corresponding veins, and their walls are essentially extensile and elastic. The small arteries and *arterioles* are essentially muscular tubes and can vary considerably in diameter. The arterioles open into the capillaries, and these are so numerous

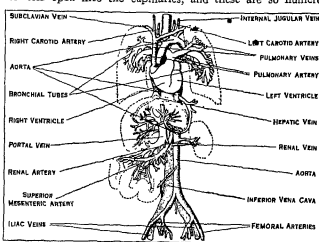


FIG. 2.—GENERAL COURSE OF CIRCULATION AND SOME OF THE PRINCIPAL VESSELS

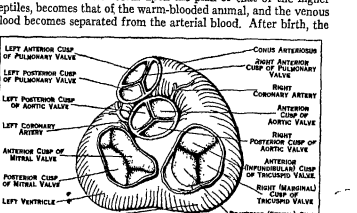
that each organ may be regarded as a sponge full of blood. The skeletal muscles and the muscular walls of the viscera at each contraction express the blood within them and materially influence the circulation. The whole muscular system must therefore be regarded as an accessory pump to the vascular system. The veins are of larger calibre than the corresponding arteries, and have tough and inextensile walls. The veins are not, as a rule, distended with blood to their full potential capacity. The latter is so great that the whole blood of the body can collect within the veins.

The heart and lungs are placed within the thoracic cavity, the floor of which is formed by the muscular diaphragm; the heart is itself enclosed in a tough inextensile bag, *the pericardium*, the function of which is to check over-dilatation of the heart. Below the heart, the pericardium is fixed to the central tendinous part of the diaphragm; above, it is suspended by the mediastinum. On account of this fixed position of the pericardium, the heart is prevented from oscillating.



The Valves of the Heart.—As regards the valves of the heart (fig. 3), the tricuspid guards the right auriculo-ventricular opening, and consists of three flaps of fibrous tissue covered, like all the internal surfaces of the heart, with the smooth shining membrane, *the endocardium*. The flaps are continuous at their base, forming an annular membrane surrounding the opening. The bicuspid or mitral valve consists of two cusps, and guards the left auriculo-ventricular opening. The under surface and free edge of each cusp of these valves are attached by chordae tendinae to two papillary muscles; these are pillars of muscle which rise up from the inner surface of the ventricles.

The papillary muscles and chordae tendineae pull down the diaphragm formed by the closed valves (the floor of the auricles), thus expanding the auricles and enabling the valvular as well as the muscular parts of the wall of the ventricles to approach together and force out the blood. The ventricles are never completely emptied, for some blood remains in contact with the auriculo-ventricular valves up to the end of systole and ensures their closure. The aortic and pulmonary valves consist of three semilunar, pocket-shaped cusps. A fibrous nodule is placed centrally in the free edge of each cusp, whence numerous tendinous fibres radiate to the attached borders of the cusp. Opposite the cusps are bulgings of the aortic walls—the sinuses of Valsalva. From the anterior one arises the right coronary artery, and from the left posterior the left coronary artery; these vessels supply the substance of the heart with blood.

Foetal Circulation.—The foetus has no independent respiration or digestion and therefore depends entirely on the oxygen and nutritive substances which diffuse through the placenta from the mother's blood. The arterial blood flowing from the placenta along the umbilical vein is partly conveyed to the vena cava ascendens by means of the ductus venosus and partly flows through two trunks which unite with the portal vein returning the blood from the intestine into the liver, thence to be carried back to the vena cava by the hepatic veins. The arterial blood flowing from the placenta becomes mixed in the vena cava with the venous blood which has returned from the trunk and the lower extremities. In the right auricle it would also become freely mixed with the venous blood returning from the head and upper extremities were it not for a special arrangement which impedes but does not entirely prevent this mixture.

On account of the presence of special valves (Eustachian valves), the upward arterial stream is directed into the left side of the heart through the foramen ovale—an opening in the intra-auricular septum—whilst the venous current from the superior vena cava is directed into the right ventricle. When the ventricles contract, the arterial blood contained in the left ventricle is expelled into the ascending aorta and thence to the head and upper extremities, while the venous blood of the right ventricle is expelled into the pulmonary artery and then through the ductus arteriosus (which branches off from the pulmonary artery before it passes into the lungs) into the descending aorta. This separation of the two streams is not perfect, but it is responsible for the fact that the upper parts of the foetus receive blood which contains more oxygen than that received by the lower parts. This is possibly the reason why the head and the arms of the foetus are always considerably more developed than the pelvis and legs. A portion of the blood flowing through the descending aorta enters the two umbilical arteries and is conveyed to the placenta, where it is re-oxygenated.

At birth, the course of circulation undergoes changes. As soon as the lungs become distended by the first respiration, a portion of blood is diverted from the pulmonary artery into the lungs. As the pulmonary circulation increases, the ductus arteriosus becomes gradually obliterated, and finally disappears. The foramen ovale between the auricles also becomes closed. The circulation, which was carried out in the foetus upon the plan of that of the higher reptiles, becomes that of the warm-blooded animal, and the venous blood becomes separated from the arterial blood. After birth, the

FROM YOUNG AND ROBINSON IN CUNNINGHAM, "TEXTBOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 3.—THE BASES OF THE VENTRICLES OF THE HEART, SHOWING AURICULO-VENTRICULAR, AORTIC AND PULMONARY ORIFICES AND VALVES

umbilical arteries and vein shrink and close up and form the ligaments of the bladder, and the ligamentumteres of the liver. The ductus venosus disappears.

Physiological Properties of the Heart.—The cardiac muscle must be regarded as endowed with four fundamental properties, viz., *Rhythmicity*, the function of originating its impulse; *Conductivity*, the function of transmitting the impulse; *Irritability*, the function of responding to stimuli; and *Contractility*, the function of developing tension which may be utilized for performing the work of circulating the blood.

Rhythmicity.—The cause of the heart beat has naturally been one of the most continued subjects of inquiry. H. Allen in 1757 was the first to show that the activity of the heart is not dependent on its connections with the nervous system. The heart is controlled and influenced by the nervous system, but this control is not essential for life The excised heart of a frog continues to beat rhythmically for days, provided that it is supplied with oxygen and prevented from drying. In the case of the warm-blooded animal, the heart is similarly capable of continuing its rhythmic contractions for some time after excision.

(1) *The Amphibian and Reptilian Heart.*—The frog's heart consists of a sinus venosus which receives the venous blood from the body, two auricles, the ventricle and the bulbus arteriosus, which divides into the two aortae. The frog's heart in the body, or after excision from the body, beats regularly, the contractions starting in the sinus, then travelling to the auricles, ventricles and bulbus.

At one time the rhythmic contraction of the heart was attributed to the action of groups of nerve cells in the sinus that were discovered by Robert Remak in 1848 Some experimental support for this theory, which is known as the "neurogenic" theory of the heart beat was given by Stannius, who demonstrated that the auricle and ventricle of the frog's heart cease to beat for some time if the sinus is tied off with a ligature, while the sinus goes on beating regularly. Further experiments have shown however that the beat of the heart cannot be ascribed to the rhythmic activity of these ganglion cells, for every strip of the heart muscle is capable of rhythmic action, whether it contains nerve cells or not. In the developing chick, the heart contracts by the 24–28th hour of incubation, while the nerves do not grow into the heart before the 6th day The inherent power of rhythmic contraction belongs to the cardiac muscle itself (the "myogenic" theory of the heart beat).

Furthermore, it belongs to every part of the heart, but there is a descending scale of this automatic power, from the sinus where it is highest to the lower parts of the ventricle where it is very slight (Gaskell) The normal sequence of contraction of the four parts is determined by the natural rhythm of these parts, but in the whole heart it is impossible for the ventricle to contract at its own rhythm because before it is ready to beat again, after a preceding contraction, it receives an impulse from the auricle. In the same way, the auricle never beats at its own rhythm; it is always subordinated to the faster rate of impulses coming from the sinus. If, however, the ventricle is electrically stimulated at a rate slightly faster than the beat of the sinus, the normal sequence of contractions becomes reversed, the ventricle now contracting first and the sinus last. All recent experiments tend to confirm the myogenic theory of the heart beat.

(2) *The Mammalian Heart.*—Although the mammalian heart has no sinus venosus, its contractions are as regular, and as independent of the nervous system as those of the lower vertebrates. Both in the heart *in situ* and in the excised heart the two auricles contract together, and after a short interval there follows the contraction of the two ventricles

In the mammalian heart, within the region where the superior vena cava opens into the right auricle, there lies a club-shaped formation known as the *sino-auricular* or the *S-A node;* functionally it is identical with the sinus of the amphibian and reptilian heart. The node is composed of slender fusiform cells with little striation It can be considered as definitely proven that, in the normal heart, the sinus serves as the centre in which the stimulus for the cardiac contraction originates The *S-A* node is, however, by no means the only place in which the impulses for the heart can originate The seat of these rhythmically recurring impulses may shift to some other portion of the heart since, as in the frog's heart, the function of rhythmicity is potentially present in every part of the heart, and the *S-A* node governs the rate of the whole heart only in virtue of its faster rate of discharge of these impulses. On this account the *S-A* node has often been described as the "pace-maker" of the heart. Other centres in which the impulses sometimes originate, and which in certain cases may gain mastery over the whole heart, are known as *ectopic* centres

It has been shown that a very distinctive system of muscle fibres lies enclosed within its own sheath beneath the endocardium. This system is known as *the conduative system* of the heart. It begins as a few strands of fibres in the region of the coronary sinus; these strands converge in a thickening which is known as the *aurículo-ventricular* or the *A-V node;* it is composed of the same type of cells as the *S-A* node. The two nodes are not connected with each other, but are divided by the ordinary contractile elements of the auricle From the *A-V* node, a thin bundle of tissue passes through the auriculo-ventricular septum towards the ventricle. This bundle was first described by His, and is known as *the A-V bundle* On penetrating the intra-ventricular septum, the bundle divides into two branches, which pass to the right and left ventricle respectively. The two branches in turn divide and subdivide, forming an extensive arborization on the inner surface of the ventricles (fig. 4).

FIG. 4.—THE CONDUCTING SYSTEM OF THE HEART

Left ventricle, laid open to show Interventricular system, on which the course of the Auriculo-ventricular Bundle and its ramifications are shown in black (after Tawara)

Various parts of the conductive system may become centres of ectopic rhythms. If the *S-A* node is destroyed or injured, or if the irritability of the *A-V* node is increased, the latter assumes the rôle of initiating the heart beat Many nervous and other influences may modify the relative irritability of the two nodes, and a shift of the pace-maker from one to the other may occur temporarily even under normal conditions. Destruction of the His bundle is equivalent to a complete functional separation of the ventricles from the auricles The ventricles develop a rhythm of their own, *the idio-ventricular rhythm* Both ventricles however continue to contract together, the centre for their activity being localized in the higher part of the bundle It is probable that still lower centres may assume a rhythmicity, but it is doubtful whether these can ever dominate the rhythm of the whole heart. Their significance consists rather in the fact that they serve to disturb some other dominant rhythm.

Thus we see that every part of the heart may serve as a centre of origin of an impulse. The natural rate of the discharges of these centres is in the following descending order: the *S-A* node, the *A-V* node, the bundle, its branches and muscle. If several centres are active simultaneously, the rate of the heart as a whole will be dominated by that centre which discharges most frequently.

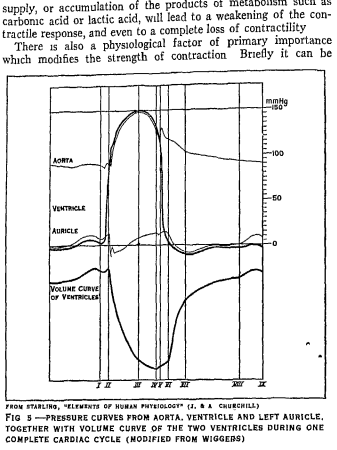
The "Normal" Heart Rate.—The normal heart rate presents considerable variations in different individuals and in different species of animals. For man it may be estimated at 68 to 76 beats per minute, and for woman 74 to 80; but the normal rate for some individuals may be much lower (50) or much higher (90). Small animals as a rule have a higher heart rate than large animals, *e.g.*, elephant 25–28, horse and ox 36–50, sheep 60–80, dog 100–120, rabbit 150–180, mouse 700; small birds like the canary have the extremely high rate of 1,000 beats per minute. Usually in man, under normal conditions, the heart rate declines with age. While at birth it is about 140, it is 100–110 at the age of 5; in childhood it is about 90, and in the adult about 70. In old age it accelerates slightly and becomes about 80.

Conductivity.—The impulses which originate in the *S-A* node spread along the ordinary muscular tissue to every part of the auricles. The rate of conduction in the auricle ranges from 600–1,200 mm. per second. In its fan-like spread, the excitation wave reaches the *A-V* node There is no indication of a preferential path of conduction between the two nodes, so that the impulse travels at the same rate over the auricle and reaches the *A-V* node about 0·03 second after the origin of the impulse. In the *A-V* node, the rate of conduction is considerably slower, the impulse passing the node at about 150–200 mm. per second Once it has passed the node, the impulse travels rapidly down the

bundle and its ramifications at the rate of about 5,000 mm per second.

The slow conduction in the *A-V* node and the rapid conduction in the bundle tissue ensure two important features of cardiac activity. On account of the former, auricular contraction is given time to end before the onset of the ventricular contraction, and on account of the latter the impulse arrives at every part of the ventricle at approximately the same time. Thus the whole ventricular muscle contracts approximately at the same time, which is a condition necessary for the development of a high pressure in the ventricular cavities.

Irritability.—When a skeletal muscle is stimulated by an increasing strength of electrical stimulus, it responds by an increasing strength of contraction, until a certain maximum is reached. A heart under the same conditions gives a contraction which is maximal for a given condition of the heart in response to the first effective stimulus; further increase in the strength of the stimulus does not lead to an increase in the strength of the response Thus difference between the skeletal and the cardiac muscle is not due to fundamentally different properties, but depends on the fact that in cardiac muscle the muscle fibrils are in free inter-communication with each other, and in this way a stimulus which originates in one part spreads over the whole of the organ, in the skeletal muscle, however, the contractile fibrils are collected into muscle fibres which are separated by the homogeneous coat of the sarcolemma. Since the threshold value of a stimulus which will evoke contraction is different for the different muscle cells, it is only to be expected that a greater number of these cells will contract in the skeletal muscle when the stimulus is strengthened, the result being a stronger total effect of contraction of the muscle. In the heart, when a stimulus evokes a contraction of a few fibres, this contraction will spread over the whole heart, so that with increase in the stimulus there is no further strengthening of the contraction. This behaviour of the heart is known as the *All or None Law.* It is most evident in the cardiac muscle, but is not peculiar to it.



The Refractory Period.—The irritability of the heart undergoes rhythmical variations which are determined by the heart beat itself. Like all excitable tissues, the heart exhibits the phenomenon of the *refractory period*, which is a period of loss of irritability following each impulse which evokes a contractile response. In the heart this period is extremely prolonged. It lasts as long as the contraction of the heart. If a second stimulus is applied to the heart during the contraction which is evoked as a response to the first stimulus, it is found that it has no effect. In the skeletal muscle, on account of the fact that the refractory period is shorter than the time occupied by the contraction, a second stimulus evokes a second contraction, or a summation of the two contractions. The period of complete loss of irritability is followed by gradual recovery, after which there is a phase of super-normal irritability before it returns to the normal.

The length of the refractory period depends in the first place on the strength of the contraction of the heart. Thus drugs and physiological conditions which strengthen the heart beat also increase its refractory period. Of greater significance, however, is the relation of the refractory period to the rate of the heart beat. Lewis found that the duration of the refractory period of mammalian auricular muscle contracting 100, 150 and 250 times per minute was 0·2, 0·15 and 0·01 sec. respectively.

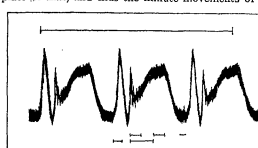
It is obvious that as a result of the shortening of the refractory period the heart is able to respond to more rapid rates of excitation than would otherwise be possible. As soon, however, as stimuli occur at intervals which are shorter than the refractory period alternate stimuli will fail to evoke any response, the heart beating at a *half-rhythm* or 2:1 response. The change from a 1:1 to a 2:1 response does not occur abruptly. Between these rates there exists a phase in which large and small beats alternate; with further acceleration of the stimulation, some beats are dropped, and with a still further acceleration a regular 3:1 rate sets in. This stage of irregular response is due to the fact that apparently all the parts of the cardiac muscle have not the same minimal refractory period, and consequently at some definite rate of excitation parts of the heart will contract in response to every stimulus, while other parts will respond by a 2:1 rate.

Contractility.—The strength of contraction of the heart is independent of the strength of the stimulus It is, however, highly dependent on the condition of the cardiac muscle. Any interference with the nutrition of the heart, inadequacy of the oxygen supply, or accumulation of the products of metabolism such as carbonic acid or lactic acid, will lead to a weakening of the contractile response, and even to a complete loss of contractility

There is also a physiological factor of primary importance which modifies the strength of contraction Briefly it can be

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG 5.—PRESSURE CURVES FROM AORTA, VENTRICLE AND LEFT AURICLE, TOGETHER WITH VOLUME CURVE OF THE TWO VENTRICLES DURING ONE COMPLETE CARDIAC CYCLE (MODIFIED FROM WIGGERS)



stated that, other conditions being equal, the greater the filling of the heart during diastole, the stronger is the following systole. This dependence of strength of contraction is so marked and is of such importance for the whole circulation that Starling named it the "Law of the Heart." It must be remembered, however, that it is not a feature peculiar to the cardiac muscle alone; it belongs to all contractile tissues, whether heart, skeletal muscle or plain muscle, but in the heart it is of a greater immediate vital importance. The practical significance is obvious; it enables the heart to eject the amount of blood which it receives during diastole whether small or large, and thus enables the heart to adapt its beat to considerable variations of the blood flow without changing its rate. A dog's heart weighing 50 grams, can put out 100 or 3,000 cc. of blood per minute without changes of the heart rate.

This remarkable adaptation is due to the fact that the larger the output, the more the heart will be filled during each period of relaxation (diastole), and hence its contraction (systole) will be stronger, so that the heart will empty itself of the extra amount of blood. When a heart is in good condition, it performs a given amount of work with a smaller diastolic volume than when the contractility of the heart becomes impaired. The same work may be performed in both cases, but in the second case in order to do the work the heart has to dilate, because at the previous diastolic volume its contractions would be too weak. The dilation of the heart at constant work is thus the first sign of impairment of its functions.

Sequence of Events in the Cardiac Cycle.—The time relation between the different events occurring during a cardiac cycle can be most satisfactorily determined by measuring pressure changes in the different cavities of the heart and in the aorta.

The apparatus almost universally used for this purpose is known

as the optical manometer. It consists of a small glass or metal tube which can be introduced directly into one of the cavities of the heart. The tube is filled with fluid, and the outside opening is sealed with a thin rubber membrane, which carries an excentrally placed small and light splinter of a mirror. A beam of light reflected from the mirror is made to play on a moving photographic plate or film, and thus the minute movements of the membrane,

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG. 6.—CURVES OF PRESSURES IN LEFT AURICLE OF CAT (AFTER STRAUB)

which are of course proportional to the pressure changes, are greatly magnified without the danger of increasing the inertia of the apparatus.

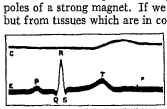
The pressure changes in the heart (fig. 5) have been described by Starling as follows:—

"The cardiac cycle begins with the contraction of the auricles, which may or may not give rise to a slight rise of pressure in the ventricles. As the auricular contraction dies away, the ventricular contraction begins at I. This causes a very rapid rise of pressure. Almost immediately after the beginning of the rise, the auriculo-ventricular valves close. The pressure then rises rapidly in the ventricular cavity. During this period, the contraction of the ventricular muscle is isometric. It is raising the pressure within the ventricles without causing any change in its contents, or in the length of the muscle fibres. Directly the pressure exceeds that in the aorta, the aortic valves open at the point marked II., and the aortic pressure thereafter rises with the ventricular pressure. During the whole duration of the ventricular contraction, the aortic pressure remains somewhat below the ventricular pressure, showing that the blood is flowing continuously from the ventricle into the aorta. The ejection of blood is at first rapid, so that the pressure in the ventricles continues to rise. As the heart gets smaller, the amount of blood ejected into the aorta becomes less than that flowing out in the unit of time through the peripheral branches, so that the pressure begins to fall in the aorta and ventricle, even though the outflow of blood is still going on.

"The ejection period may therefore be divided into two phases, that of maximum ejection and that of reduced ejection. The ventricular muscle suddenly relaxes at the point marked IV., causing a sudden fall of pressure in the ventricle and a slight fall in the aorta. The latter is, however, arrested almost at once by the closure of the aortic valves, marked by the sharp depression, the *dicrotic notch*, in the aortic tracing. The pressure in the ventricle continues to fall until at the point VI. it drops below that in the auricle and the auriculo-ventricular valves open, allowing the inflow of blood from the pulmonary veins and auricles. Between V. and VI. the relaxation is isometric, since all the valves guarding the orifices of the ventricles are closed.

"The pressure in the ventricles then continues to fall more slowly until it reaches the line of zero pressure, and remains at or near this line during the greater part of diastole. With a big inflow there may be a slight rise towards the end of diastole, which may be accentuated by the auricular contraction. If the chest is opened the pressure in the ventricle never sinks below zero during any part of diastole. In the closed chest the pressure in the heart cavities during diastole will be negative, on account of the negative pressure within the thorax."

The duration of the separate phases of the heart beat depends naturally on the rate of the beat. In all cases of change of heart rate, the period of diastole is affected relatively much more than the period of systole. Owing to the absence of valves between the auricles and the large veins, changes of pressure within the auricle will be transmitted along the veins.



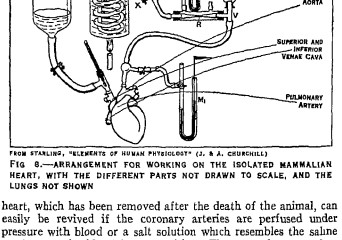
In every case the auricular pressure tracing exhibits the following features (fig. 6): (1) The first positive wave, which occurs during auricular systole. (2) The second positive wave, which is due to the sharp closure of the auriculo-ventricular valves. (3) The third positive wave, which is due to the filling of the auricles while the auriculo-ventricular valves are closed. (4) A negative wave, which is due to the rapid emptying of the auricle after the opening of the auriculo-ventricular valves. The chief function of the auricle is not to propel blood into the ventricle by its contraction, but to serve together with the big veins as a reservoir for the blood which flows in from the body but which cannot enter the ventricle while the latter is in a state of contraction.

The Apex Beat.—The pulsation which is felt over the region of the heart is known as the "apex beat," and was formerly thought to be due to the twisting forward of the apex at each systole. Its origin is, however, different. During diastole, the ventricles form a flabby flattened cone, lying against the chest wall and slightly depressed by the latter. In systole, the ventricles become hard and rigid, and assume the form of a rounded cone. This sudden change in shape and hardening of the ventricular wall pushes out that part of the chest wall which is in immediate proximity to the ventricle, giving rise to the "apex beat."

The Sounds of the Heart.—When the ear is applied to the chest above the cardiac region, two sounds may be heard; the first, which is heard most intensely over the apex, is a duller and longer sound than the second, which is heard best over the base of the heart. The first and second sounds resemble the syllables *lubb dup–lubb dup*. The first sound is of twofold origin. It arises from the sudden closure of the auriculo-ventricular valves, and from the contraction of the thick muscular wall of the ventricles. The second sound is due to the sharp closure of the auricular and pulmonary valves.

When fluid escapes through a narrow orifice, vibrations are set up in the fluid giving rise to various sounds. Under normal conditions, when the valves of the heart are closed completely, sounds produced in this way are either absent or negligible; in abnormal conditions, *e.g.*, after disease affecting the orifices of the heart or the valves, these vibrations may become loud enough to be easily heard. These murmurs or *bruits* as they are called are of great importance, for they enable the physician to judge the condition of the valves, and to determine which valve is affected.

The Electrocardiogram.—The contractions of the different cavities of the heart are accompanied by electrical changes which can be recorded if any two parts of the heart are connected to a sensitive galvanometer. The apparatus which is generally used for this purpose is the string galvanometer, in which a very delicate thread of silvered quartz or of platinum is stretched between the poles of a strong magnet. If we lead off, not from the heart itself, but from tissues which are in contact with the heart, we shall still obtain the electrical changes at each heart beat. An electrocardiogram so obtained is reproduced in fig. 7.



FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG. 7.—ELECTROCARDIOGRAM OF MAN, OBTAINED BY LEADING OFF FROM THE TWO HANDS TO A STRING GALVANOMETER. C THE CAROTID PULSE TRACING

The deflection P is due to the auricular contraction and QRS marks the beginning of the ventricular contraction. Thus the P-R interval represents the period between the auricular and ventricular contractions. The total duration of the excitatory state of the ventricle is measured by the distance between Q and T. A case of *A-V* block, as for instance in Adams-Stokes' disease, is shown at once on the electrocardiogram by the dissociation of the normal relations between the auricular and ventricular deflections. A delay in conduction of the excitatory wave is accompanied by a prolongation of the P-R interval, while a beat originating from the *A-V* node instead of the *S-A* node is immediately shown by a

shortening or even disappearance of the P-R interval. The exact origin of the T wave is not known. The electrocardiogram has become an important aid in the study and diagnosis of abnormal heart activities.

The Isolated Mammalian Heart.—The nutrition of the mammalian heart is carried out by means of the coronary arteries, which leave the aorta at the place of its origin. A mammalian

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

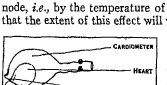
FIG. 8.—ARRANGEMENT FOR WORKING ON THE ISOLATED MAMMALIAN HEART, WITH THE DIFFERENT PARTS NOT DRAWN TO SCALE, AND THE LUNGS NOT SHOWN

heart, which has been removed after the death of the animal, can easily be revived if the coronary arteries are perfused under pressure with blood or a salt solution which resembles the saline medium of the blood in composition. This procedure was first introduced by Ludwig for the frog's heart, and by Langendorff for the mammalian heart. Sydney Ringer first determined the exact amount and type of salts necessary for the most successful survival of the frog's heart, and Locke modified Ringer's solution for the mammalian heart. With the use of such a solution, a mammalian heart can be restored to activity as long as 7 days after death. The beat of the isolated heart of a child can be restored 20 hours after death from pneumonia. The excised heart of a cat can be kept beating for 4 days. The heart of a monkey was restored after freezing the dead body of the animal.

Conditions Essential for the Heart Beat.—For perfusion experiments, a cannula is tied in the aorta pointing to the heart. The pressure of the column of fluid closes the aortic valves and the only way of escape is through the coronary arteries; after having passed through the heart muscle, the fluid flows out of the coronary veins. In this manner it is possible to study the influences directly affecting the heart beat and the coronary blood vessels.

The first and most essential condition for reviving a heart is an abundant supply of oxygen; the second is the maintenance of the perfusion fluid at a reaction similar to that of blood, *i.e.*, slightly on the alkaline side of neutrality (sodium bicarbonate is usually added for this purpose).

A third important factor is the maintenance of the temperature within physiological limits. An increase in temperature causes an increase in heart rate but at about 44° C to 45° C the beat ceases entirely. At temperatures ranging from 13°–19° C the beat ceases, but on rewarming the co-ordinated contractions are re-established. In all these cases the effect of temperature is primarily on the S-A node, and warming or cooling the node duplicates the effect of warming or cooling the perfusion fluid, except that at some stage the lower rhythm centre of the heart will begin to be dominant, whereas in the cooling of the whole heart the rhythm of all the centres becomes depressed.



The main purpose of the sodium chloride in the fluid is to keep the osmotic pressure of the fluid the same as that of blood. Calcium and potassium have however a direct influence on the contractility of the heart. After a short perfusion with a fluid that lacks calcium and potassium, the heart soon stops beating altogether. Addition of calcium salts will immediately evoke contractions, which will grow in force, but the heart will soon fail to relax completely and will gradually stop in systole. On addition of potassium salts, the heart resumes a normal beat. Excess of calcium salts leads to a systolic standstill, and excess of potassium salts leads to a diastolic standstill. The normal activity can proceed only if salts of both calcium and potassium are present in the proper proportions.

The Heart-lung Preparation.—A great advance in the study of the heart was made when Starling succeeded in investigating the heart under conditions like those of the perfused heart, but with the great advantage that the heart performed work and pumped blood in exactly the same way as in the whole animal. The arrangement of the method is shown in fig. 8.

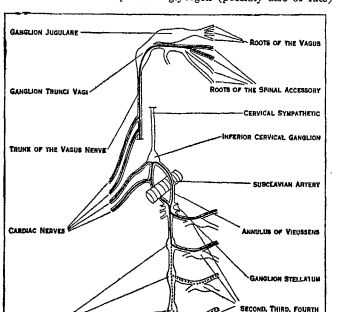
Artificial respiration being maintained, the chest is opened under an anaesthetic. Cannulae are placed in the brachiocephalic artery and the superior vena cava. All other blood vessels going to and from the heart are tied off. The blood emerging from the heart is made to flow against an artificial variable resistance (R), through a glass spiral immersed in warm water, into a reservoir. From the reservoir the blood flows through the superior vena cava into the heart. The aortic blood pressure can be varied in this preparation by changing the artificial resistance against which the heart is made to work.

The output of the heart can be measured at any time by opening the tube X, clamping tube Y, and allowing the blood to flow into a graduated cylinder. The volume changes of the heart at each beat can be measured by the so-called cardiometric method. A glass cardiometer of the shape shown in fig. 9 is fitted over the beating heart. The opened pericardium is tied around the lip of the cardiometer, which is then connected with a tambour with a slack rubber membrane. The movements of this membrane are recorded by a lever on the smoked surface of a revolving drum. The difference between the diastolic and the systolic volume thus recorded is obviously equal to the amount of blood put out by the two ventricles during a single heart beat.

This preparation enabled Starling and his co-workers to study the main features of the physiological activity of the heart. It was found that the heart itself cannot modify the blood flow and that, within wide variations of the heart rate and of the arterial resistance against which the heart beats, the output remains constant provided the inflow is not changed. This means that the heart will adapt the strength of its beat within very wide limits, and will perform the work required if it is within the functional capacity of the organ. If the inflow into the heart is say 1,000 cc. a minute, this output will be maintained if the heart rate is 100 or 200 beats per minute, or if it has to beat against a pressure of 60 or 160 mm. of mercury. Increase in the heart rate does not modify the output, but it increases the maximum amount of blood which the heart is able to expel, since at the faster heart rates the inflow of blood can be increased without causing over-distension of the ventricles. Another important observation made by Starling was that, in the heart-lung preparation, the heart rate is independent of the pressure against which the heart works and of the output. The heart rate is here determined by the temperature of the S-A node, *i.e.*, by the temperature of the circulating blood. It is clear that the extent of this effect will vary from heart to heart, depending on the natural rhythmicity of the node.

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG. 9.—HENDERSON'S GLASS CARDIOMETER.



The Work of the Heart.—The energy of the contraction of the heart is expended (*a*) in forcing a certain amount of blood against a certain resistance presented by the arterial pressure, and (*b*) in imparting a certain velocity to the blood. The work done by each ventricle can be calculated from the formula:

$$W = Mr + \frac{Mv^2}{2g}$$

Where W is the work done, M is the mass of blood expelled at each beat, r is the mean arterial pressure, v is the velocity at the root of the aorta, and g the factor of acceleration. The work of the right ventricle is approximately $\frac{1}{3}$ of that of the left. The work of both ventricles in the human heart at rest is about 100 gram-

meters per beat, which is equivalent to about 10,000 kilogram-meters in 24 hours. During very strenuous muscular exercise when the output is considerably increased, the work of the heart per beat is about 400 gram-meters, or 80,000 kilogram-meters in 24 hours This rate of work could probably be maintained for not more than a few minutes

The energy required for the cardiac contraction is derived from the oxidation of the deposits of glycogen (possibly also of fats)

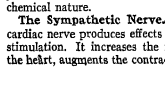
FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG. 10.—DIAGRAM OF CARDIAC INHIBITORY AND ACCELERATOR FIBRES IN THE DOG (FROM FOSTER)

within the heart itself. It was found by Lovatt Evans that, on increasing the arterial pressure from 80–140 m.m. of mercury, the oxygen consumption of a heart was increased from 228 to 404 cc. per hour; and on increasing the output from 9·3 to 92 litres per hour, it increased from 155–649 cc. per hour. The maximum efficiency of the heart is of the same order as that found for skeletal muscle, namely 20–28%.

The Nervous Regulation of the Heart Beat.—In the vertebrates, the heart is supplied with two sets of nerve fibres; those which pass from the central nervous system in the vagus nerve, and those which pass in the sympathetic nerves (fig. 10). The cardiac fibres of the vagus terminate around nerve cells situated in the heart itself (preganglionic fibres); the ganglionic cells serve as relays from which new fibres (postganglionic fibres) emerge and run directly to the cardiac muscle and to the *S-A* node. The sympathetic fibres leave the spinal cord by the anterior roots mainly of the second and third dorsal nerves, run in the white *rami communicantes* to the Stellate ganglia where they end; from the Stellate ganglia, postganglionic fibres begin, which go to the various parts of the cardiac muscle.

The Vagus Nerve.—In 1845 the brothers Weber made the important discovery that stimulation of the vagus nerve retards or even arrests the heart beat. The cardio-inhibitory nerves have since then been found in all classes of vertebrates and in many invertebrates. During a stimulation of the vagi, the heart beat is considerably retarded or stops altogether, and as the result of this the arterial blood pressure falls. Blood accumulates on the venous side of the heart and is not forced out in sufficient amount to maintain the blood pressure. If the stimulation of the vagus is prolonged, the heart often begins to beat again with a slow rhythm; this beat is seen to be confined to the ventricles only, the auricles still remaining at a standstill. We speak of such a beat as an "escape." The ventricle is really beating at its own idio-ventricular rhythm in response to impulses originating within itself.



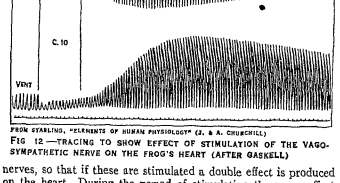
A detailed study of the effect of vagus stimulation on the heart has shown that it affects all the four fundamental properties of the heart muscle (fig. 11). By inhibiting the S-A node, it depresses the rhythmicity, by affecting the conductive system, it retards the propagation of the impulse in the auricular muscle and in the A-V bundle; by affecting the muscle proper, it diminishes its contractility and each beat becomes weaker, in consequence of which the refractory period of the heart is shortened; and finally it diminishes the irritability of the heart. Whether the vagus has a direct action on the mammalian ventricle is still doubtful.

If both vagi are cut, the heart immediately begins to beat faster, showing that under normal conditions a continuous stream of impulses passes down the cardio-inhibitory nerves, which do not allow the heart to beat at its full independent rate.

For obvious reasons, section of the vagi cannot be performed in man, but we have at our disposal a drug which paralyses the peripheral nerve endings of the postganglionic vagal fibres, namely atropine, an alkaloid obtained from belladonna.

The question as to what controls the normal tone of the vagi has been the subject of many researches, and at present we know of several factors that are concerned. Amongst them we must mention first the blood pressure. Marey was the first to show that, other conditions being equal, the vagus tone increases with increase in the blood pressure. This effect is probably not due to the direct stimulation of the vagus centre in the medulla, but to stimulation by high blood pressure of special sensory endings in the aorta, in the ventricles, and in some of the blood vessels going to the brain. The sensory impulses reflexly retard the heart by stimulation of the vagus centre. Changes in the composition of the blood and various drugs may also affect the vagus centre. Asphyxia, and the action of morphine may be mentioned as such centrally acting stimuli; they retard the heart, but only if the vagi are intact. Reflexes from various sensory nerves may stimulate or inhibit the vagus centre; for instance, inflation of the lungs diminishes vagus tone (the Hering Breuer reflex); increase in the output of the heart has the same effect (Bainbridge reflex). Stimulation of the respiratory passages, as in the case of inhalation of an irritant volatile substance, retards the heart, and high intracranial pressure has the same effect. There are also stimuli which may excite the peripheral nerve endings of the vagi in the heart itself, *i.e.*, substances which will act even after section of the vagi, but not after injection of atropine—for instance bile salts, which enter the general circulation in the case of jaundice.

The intimate mechanism by means of which the vagus produces its effect on the heart has been a field of intense experimentation and theorisation. It has been suggested that the vagus impulses produce "interference" waves with the impulses originating in the S-A node; that the vagus is a nerve which abolishes the katabolism or disintegration processes associated with activity, and leads to anabolism or reconstruction processes; that on account of similarity in the effect of stimulation of the vagus with that of potassium salts, the vagus possibly liberates free potassium from a colloidal combination or from an adsorbed state from the proteins. According to Loewi, the vagus acts by producing some chemical substance (of the choline type) which is the active factor.



FROM STARLING "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG. 11.—BLOOD PRESSURE TRACING FROM CAROTID OF A DOG SHOWING EFFECT OF EXCITATION OF VAGUS (BETWEEN THE ARROWS)

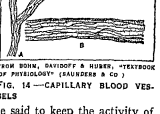
His experiments support the theory most brilliantly. If a perfused frog's heart is stopped by stimulation of the vagus, and if the perfusion fluid is collected from the heart and transferred to a beating frog's heart, the second heart will show all the effects of vagus stimulation. The chemical substance responsible has been extracted and dried, but has not yet been obtained in a sufficiently pure form to establish its chemical nature.

The Sympathetic Nerve.—Stimulation of the sympathetic cardiac nerve produces effects which are the reverse of the vagus stimulation. It increases the rate by raising the rhythmicity of the heart, augments the contractions, increases the rate of conduc-

tion of the impulse, and raises the irritability of the heart. On account of the increased strength of contraction, the refractory period becomes somewhat more prolonged than that normally associated with the given heart rate. The sympathetic nerves are much less easily tired than the vagus fibres and have a longer after-effect. In most animals the inhibitory and the accelerator fibres, which were discovered by Cyon, become mixed in the cardiac

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG 12.—TRACING TO SHOW EFFECT OF STIMULATION OF THE VAGO-SYMPATHETIC NERVE ON THE FROG'S HEART (AFTER GASKELL)



nerves, so that if these are stimulated a double effect is produced on the heart During the period of stimulation the vagus effect predominates, but after the end of stimulation the sympathetic effect becomes apparent, and the heart accelerates and the beat increases in strength (fig. 12).

Stimulation of either set of fibres before they are mixed together produces effects typical of one or the other only. In the dog, whose normal heart rate is about 100 beats per minute, stimulation of the accelerator nerves may increase it to 260 beats, and at the same time the strength of each contraction will be increased. The latter effect is most marked in hearts which have begun to fail and which are therefore dilated.

The question whether, under normal conditions, the accelerator fibres are in a state of tone like that of the inhibitory fibres of the vagus is not definitely settled. It is customary to assume the existence of such a tone, but to consider it as less pronounced than that of the vagus. In most experiments, extirpation of the Stellate ganglia leads to a retardation of the heart Many observers have shown that the tonic conditions of the two centres stand in a reciprocal relation to one another. Whenever the tone of the inhibitory fibres is increased, that of the accelerator fibres is diminished; thus the final effect on the heart will be an algebraical summation of the two influences. The tone of the accelerator centre is greatly increased in asphyxia, in cerebral anaemia, in the case of various sensory stimuli (especially painful stimuli), and probably in the case of muscular exercise. In the first two states, which are pathological, the tone of both nerves is increased simultaneously. Thus, in the absence of the sympathetic nerves, asphyxia produces retardation of the heart by stimulating the vagus, and in the absence of the vagus it produces an acceleration. In the presence of both nerves, it first retards the heart and may even arrest it until the vagi become paralysed, after which the heart greatly accelerates above the normal, because of the co-existent stimulation of the sympathetic centre.

The Suprarenal Gland.—It has already been mentioned that the influence of the vagus can be modified by stimuli affecting the centre, or by substances which stimulate or paralyse the peripheral nerve endings of the vagus within the heart itself. In the case of the sympathetic innervation, the organism normally produces a chemical substance which stimulates all the sympathetic nerve endings.

The production of this substance is the function of the suprarenal (or adrenal) gland, and the substance has not only been obtained in a chemically pure state, but has also been synthesised. It is known as *adrenaline* or suprarenin. Adrenaline is active in very small amounts, concentrations of one in one hundred millions producing a strongly exciting effect. Under normal conditions, however, the quantities entering the blood are probably too small to have any physiological effect. The liberation of adrenaline is under the influence of the splanchnic nerves, section of which diminishes the secretion, while stimulation greatly increases it Certain drugs, asphyxia, various emotions such as fear or anger lead to an excessive production of adrenaline Directly the adrenaline reaches the heart, even when its connections with the nervous system are all severed, the contractions become considerably faster and extremely energetic, and the heart becomes able to cope with a greater strain (either in the shape of arterial resistance or increased venous inflow) than it could do without the stimulus of adrenaline

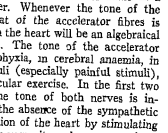

FIG. 14.—CAPILLARY BLOOD VESSELS

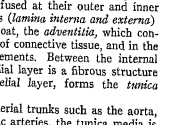
To summarize, we may state that the heart beat is a property of the heart itself, and as such it is independent of the nervous system The latter may however be said to keep the activity of the heart under constant supervision, moderating its action by means of the vagus, and increasing it by means of the sympathetic nerves, thus adapting it to the general requirements of the body. Under conditions of great physical strain, the organism is able to make use of its store of adrenaline, which assists the nervous regulation of the heart beat. Thus, even after complete denervation of the heart, a certain amount of adaptation of its activity is still possible.

THE BLOOD VESSELS



Structure of the Blood Vessels.—The haemodynamic conditions in the various parts of the vascular system are very different, and it is not surprising to find that the structure of the various blood vessels is accordingly different. A cross-section of a blood vessel shows several coats. The inner consists of flattened endothelial cells and is common to all vessels. The second coat, the *tunica media*, varies greatly in thickness; it contains most of the contractile elements of the arterial wall (smooth muscle fibres) and a variable amount of elastic fibres The latter have in general a circular arrangement; they are fused at their outer and inner surfaces to form elastic membranes (*lamina interna and externa*) Outside the media, lies the third coat, the *adventitia*, which consists in the arteries almost entirely of connective tissue, and in the veins principally of contractile elements. Between the internal elastic membrane and the endothelial layer is a fibrous structure which, together with the endothelial layer, forms the *tunica intima*.

The Arteries.—In the great arterial trunks such as the aorta, the pulmonary, the carotid and iliac arteries, the tunica media is divided by elastic fibres and membranes into a large number of concentric layers containing (especially in the aorta) only a few muscle fibres. The adventitia of the large arteries is also composed of fibro-elastic tissue, but its structure is looser and the fibrous tissue is more abundant. The medium-sized arteries differ in structure from the larger ones in that the elastic elements of the intima and media are replaced to a considerable extent by non-striated muscular fibres (fig 13) To this type belong the majority of the arterial vessels.

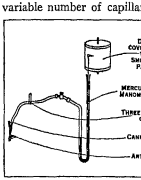
FIG. 13.—TRANSVERSE SECTION THROUGH ONE OF THE SMALLER OF THE MEDIUM SIZED HUMAN ARTERIES



FROM BOHM, DAVIDOFF & HUBER, "TEXTBOOK OF HISTOLOGY" (SAUNDERS & CO.)

FIG 15.—TRANSVERSE SECTION THROUGH A SMALL HUMAN VEIN

The Capillaries.—These (fig. 14) consist solely of a single layer of endothelial cells, which present little resistance to the passage of substances dissolved in the blood, such as oxygen, carbon dioxide, sugar and salts. According to some observers, the cells forming the capillary wall are contractile; according to others, the actual contractile elements are special Stellate cells which encircle the capillaries. But whatever the mechanism, the

contractility of the capillaries is unquestionable, and must play a considerable part in regulating the blood flow through an organ The average length of capillaries is between 0·4 and 0·7 m.m.; in most organs they freely anastomose with each other, forming a more or less loose network.

The Veins—The smallest veins result from the fusion of a variable number of capillaries. They assume a connective tissue coat, the adventitia (fig. 15), and with increase in size muscle-fibres appear in the form of a badly defined media. Some of the larger veins, such as the brachial and subcutaneous veins, have a better developed muscular layer, while in others (the jugular, the subclavian, the veins of the dura and pia mater) the media is entirely lacking. Generally speaking, the muscular and elastic elements are much less prominent in the veins than in the arteries, and they contain a preponderance of inelastic connective tissue fibres. In many veins the adventitia shows an inner longitudinal muscular layer All subcutaneous veins and some internal veins are supplied with valves which restrict any possible back flow. The valves of the veins are reduplications of the intima, and the greater part of the valvular structure consists of fibrous connective tissue and elastic fibres.

FIG 16 —APPARATUS FOR TAKING BLOOD PRESSURE TRACING

The Blood Pressure.—It has long been known and can easily be demonstrated that the blood is under different pressures in the various parts of the vascular system. When an artery is cut, blood flows out with great force in a series of jerks which are synchronous with the heart beat. When a large vein is cut, the blood also flows out rapidly, but the stream has very little force.

The first measurement of arterial pressure was made by the Rev. Dr. Stephen Hales. ("Statical Essays, containing Haemastaticks" 1733.)

Since Hales' work, the chief improvements in the method have been the application of the mercury manometer by Poiseuille, the invention of the recording manometer and the kymograph by Ludwig (figure 16), and the introduction of the more accurate membrane manometer by Hürthle and Frank.

FROM NOWELL, "TEXTBOOK OF PHYSIOLOGY" (SAUNDERS & CO.)

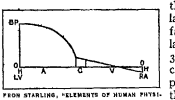

FIG. 17 —A RECORD OF ARTERIAL BLOOD PRESSURE TAKEN WITH A MERCURY MANOMETER FROM THE CAROTID ARTERY OF THE RABBIT, RECORDED IN SECONDS

The manometer of Ludwig consists of a U-tube which is half-filled with mercury. On the surface of the mercury of one limb is a float from which a stiff light rod projects, bearing on its upper end a writing point which is made to write on the smoked surface of a revolving drum The other limb of the manometer is connected by means of a glass or metal cannula to the artery? The tube between the artery and the manometer is filled with a solution of some anticoagulant salt (sodium citrate, magnesium sulphate).

The mercury manometer allows a direct reading of pressure, but on account of its inertia it does not accurately record rapid changes in the pressure. The membrane manometer, which is merely a tube filled with fluid and sealed at one end with a stretched rubber membrane, records rapid changes in pressure more accurately, but each membrane requires special calibration if absolute values are desired The venous pressure is recorded by a similar method, but with a water manometer or a manometer with a lightly stretched membrane.

The highest pressure, which occurs while the blood is passing from the heart into the aorta, is called the *systolic arterial pressure*, and the pressure at the end of diastole is the *diastolic pressure*; the range between these two extremes is known as the *pulse pressure* In the dog, with a mean arterial pressure of about 120 mm of mercury, the systolic pressure may be as high as 160 mm., and the diastolic pressure as low as 65 mm.; here the pulse pressure would be 95 mm. of mercury. By taking the pressure at different parts of the vascular system, we obtain a result which is diagrammatically represented in figure 18.

Close to the heart, the mean arterial pressure is about 100–120 mm. It falls only slowly in the large arteries, but between the smaller arteries and the capillaries there is a very extensive fall of pressure, so that the capillary pressure is only about 10 to 30 mm. of mercury; from the capillaries to the veins the blood pressure falls steadily, until in the large veins near the heart it may be negative

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG 18 —BLOOD PRESSURES IN VARIOUS PARTS OF VASCULAR SYSTEM

A. In the arteries, C. capillaries, and V. in the veins

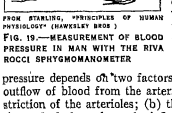
The arterial blood pressure in man is determined by means of the Riva Rocci sphygmomanometer (figure 19), which consists of a rubber bag that can be strapped round the upper arm. The bag is connected with a manometer, and the pressure in the bag is raised by pumping air into it The pressure at which all pulsations disappear in an artery below the place of compression represents the systolic pressure. The diastolic pressure can also be determined by the same apparatus.

To determine the venous pressure in man, an apparatus is used which is constructed on the same principle as the sphygmomanometer. The skin is greased, and an annular rubber bag is placed over a vein and cemented over with a glass plate (figure 20). On blowing air into the bag, the pressure can be determined at which the vein collapses. The blood pressure in the capillaries is usually determined by the von Kries method (figure 21). A small glass plate is placed over the skin; attached to this plate is a small scale pan on which weights are placed until the pressure is just sufficient to blanch the underlying skin.

The mean blood pressure in the circulatory system of a young adult man in the horizontal position was found to be as follows:

Large arteries . . .	90 mm. mercury (65–110)
Medium arteries . . .	85 mm
Capillaries . . .	10–30 mm.
Small veins	9 mm.
Large veins	0–8 mm.

From this we see that the largest drop in pressure occurs between the small arteries and the small veins This shows that the main resistance of the vascular system is situated in the arterioles The arterioles are always in a semi-contracted state (tone), partly determined by impulses coming from the central nervous system, and partly by the properties of the plain muscles of which they are composed Since the total vascular bed of the capillaries is very much larger than that of the arterioles, the main drop in the pressure must occur just past the arterioles. The mean arterial pressure depends on two factors: (a) the total resistance to the outflow of blood from the arterial system, *i.e.*, the state of constriction of the arterioles; (b) the output of the heart in a given time, which depends on the inflow of blood.

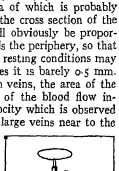


FROM STARLING, "PRINCIPLES OF HUMAN PHYSIOLOGY" (HAWKSLEY BROS.)

FIG. 19.—MEASUREMENT OF BLOOD PRESSURE IN MAN WITH THE RIVA ROCCI SPHYGMOMANOMETER

The Arterial Pulse—Owing to the elasticity of the arteries, every systolic rise of the blood pressure produces an expansion of their walls, which can be felt by placing a finger on any superficial artery It is obvious that the nearer the artery is to the

heart, the more pronounced will be the pulse The rate of transmission of this pressure wave will depend on the elasticity of the arteries If they were rigid, no pulse could be recorded. The more elastic the arteries, the slower will be the transmission of pressure along them Under normal conditions, the pulse wave in man is transmitted at the rate of about 7 meters per second, but if the arteries are initially stretched by high pressure their walls will tend to approximate to rigidity, and therefore the propagation of the pulse wave will be faster. It is important not to confuse the velocity of the pulse wave, which is simply a transmission of pressure along the tubes, with the velocity of the blood flow. The latter is of the order of about 0 5 meters per second in the aorta, and considerably less in the smaller blood vessels



FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J & A CHURCHILL)

FIG 20 —APPARATUS FOR DETERMINATION OF VENOUS PRESSURE

The elasticity of the arterial system determines another important feature of the blood flow; it is the cause of the continuity of the blood flow (except for slight increases during systole and decreases during diastole), in spite of an intermittent ejection of blood by the heart into the aorta A sufficient amount of blood is accommodated in the arterial system to maintain a flow into the capillaries during the whole period of diastole. In the capillaries the pulse disappears, and the blood flow is continuous. Arterial pulse tracings recorded by means of sphygmographs (a system of levers which can be placed on a pulsating artery, the pulsation of which is thus registered on a moving plate with blackened surface) show various secondary undulations, either in the ascending part of the wave (anacrotic pulse), or in the descending (catacrotic pulse). These are partly due to extra vibrations set up in the arterial wall by the inrushing blood, and partly to pressure waves reflected from the periphery

The Velocity of the Blood Flow.—This depends on the relation between the bore of the blood vessel and the amount of blood passing through it in a unit of time. The total area of the cross sections of the arterial system gradually increases from the aorta to the periphery. The increase in area is especially great when the arteries break up into capillaries, the area of which is probably over a thousand times larger than that of the cross section of the aorta. The velocity of the blood flow will obviously be proportionately reduced the further we go towards the periphery, so that while in the aorta the mean velocity under resting conditions may be about 500 mm per second, in capillaries it is barely 0·5 mm. per second As the capillaries join to form veins, the area of the vascular bed diminishes and the velocity of the blood flow increases; however, it never reaches the velocity which is observed in the aorta since the cross section of the large veins near to the heart is about double that of the aorta.

Intensity of the Circulation.—The amount of blood received by the heart from the veins and passed to the arteries in a unit of time, cannot be measured directly. However, a knowledge of the cardiac output is of considerable importance because it controls the amount of oxygen carried to the tissues and the rate of the removal of various products of metabolism from the tissues. The great value of the study of the cardiac output of man and animals has only been realised comparatively recently, and there still remains much to be done; nevertheless methods of sufficient precision have been worked out, and the main factors governing the cardiac output are gradually being disclosed

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J & A CHURCHILL)

FIG. 21 —APPARATUS OF VON KRIES FOR MEASURING CAPILLARY BLOOD PRESSURE

Zuntz calculated the output by comparing the difference in the oxygen content of the arterial and venous blood with the amount of oxygen consumed in a given time. For instance in a horse weighing 360 kilo , 2,735 cc. of oxygen were consumed per minute; the arterial blood contained 10·33% more oxygen than the venous. Since every 100 cc. of blood that passed through the lungs had taken up 10 33 cc of oxygen, 2,733 cc of oxygen had been taken up in the course of one minute by $\frac{100 \times 2733}{10\ 33} = 26{,}457$ cc of blood.

Krogh modified this method by making the animal or man breathe a gas which was harmless and easy to detect, viz , nitrous oxide He knew how much of the gas could be absorbed by 1cc of blood, and was therefore able to calculate the cardiac output by determining the amount of gas taken in during one minute Recently other methods have been introduced which are claimed to be more exact In one of them, ethyl iodide is the gas absorbed, and in another the principle of Zuntz is modified and the output is calculated by comparing the carbon dioxide content of the arterial and venous blood with the amount of carbon dioxide given off in a unit of time

Cardiac Output in Man.—In man, under conditions of rest, the cardiac output varies in different individuals between about 3½ and 6 litres of blood per minute, that is between 60 and about 110 cc for each heart beat The cardiac output, *i e* , the inflow of blood into the heart, as in the heart-lung preparation, is within wide limits independent of the heart rate It primarily depends on (a) how freely the blood passes from the arterial system through the tissues into the venous system, *i.e* , on the peripheral resistance; and (b) the power of the heart to pump the inflowing blood into the arteries; and (c) the capacity of the vascular system relative to the amount of blood When the arterioles dilate, the blood passes quickly through the organs and, since the capacity of the vascular bed will be changed but little, the blood will reach the heart during the next few beats in a larger amount The heart will therefore force more blood into the arterial system, and thus within limits prevent a fall of arterial blood pressure, which would have taken place if the arterioles dilated without causing an increase in the blood flow

If we turn now to the second way in which the output may be increased, namely the strengthening of the heart beat, it is clear that, if the pumping action of the heart becomes inadequate, blood will stagnate on the venous side, and the output will diminish. If the heart beat is improved by nervous or pharmacological agencies, there will be better emptying of the venous side, and a consequent increase in the circulation rate.

The third factor governing the output is the capacity of the vascular bed relative to the amount of blood. This factor can be appreciated by considering the tremendous capacity of the capillary system Krogh has shown that $\frac{1}{20}$ to $\frac{1}{70}$ of a muscle is made up of capillaries, and in the heart there is at least one capillary to every muscle fibre If all these capillaries lost their tone, the animal would literally bleed into them, the arterial and venous system would become empty, and the output of the heart would fall to vanishing point

The amount of blood in the circulation and the capacity of the vascular bed should not be considered as rigidly fixed for any individual The vascular system is in a perpetual state of variation on account of the continuous changes of the vasomotor tone. It is obvious that unless vasoconstriction is compensated for by a simultaneous vasodilation elsewhere it will lead to a change in the resistance as well as a change of capacity. Arterial vasoconstriction will chiefly affect the resistance, while even small changes in the tone of the enormous capillary bed will mainly affect capacity. Thus on account of these changes of capacity more or less blood may be in active circulation, and more or less blood may be left behind to fill the vascular bed

Spleen, Lungs and Other Factors.—There are however two organs which play a predominant rôle as reservoirs of blood, namely the spleen and the lungs, the difference being that the spleen seems to change its capacity mainly as the result of active contraction and relaxation, while the lungs play a purely passive rôle and act only because of the very great elasticity of their blood vessels. With every increase in the pulmonary blood pressure or with a certain decrease in the intrathoracic pressure, the pulmonary blood vessels contain more blood, and therefore less blood is available for the systemic circulation. On the other hand, the capacity of the spleen is to a much greater extent independent

of the blood pressure, the changes in its vascularity being due to active contractions of its muscular frame. These contractions seem to be specially adapted to meet the requirements of the whole organism Whenever, for instance, more blood is needed in circulation, as when the animal loses blood or when blood goes to fill widely dilated vascular areas of other organs, the spleen contracts. This also happens in anoxaemia following diminution of the oxygen supply, or during diminution of the oxygen-carrying power of the blood as in the case of carbon monoxide poisoning

As we have already seen, the vascular resistance, the fitness of the heart and the vascular capacity are the three main factors which determine the blood flow in the whole animal There are however accessory factors, the chief of which are the respiratory movements and the contractions of the skeletal muscles. Any increase in respiratory movements leads to a more negative pressure in the thorax, and therefore to a better aspiration of blood from the periphery into the large veins and the heart. This is probably the main cause of the so-called respiratory variations of the blood pressure, during inspiration the inflow into the heart is increased, and after a certain lag the output is also increased. The rhythmic contractions of the skeletal muscles press the blood from the capillaries to the veins, the back-flow of blood being prevented by the valves of the veins.

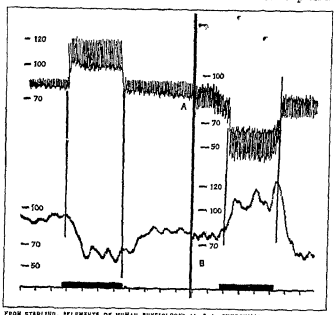
The Nervous Control of the Blood Vessels.—During increased activity, an organ requires more oxygen Theoretically this could be accomplished by an increased degree of de-oxygenation of the blood without a change in the blood flow, or by an increase in the blood supply without any change in the degree of deoxygenation. The organism uses both methods, but the first in preference. In some cases the increase in the blood supply is such as to overcompensate the need, so that, although the oxygen consumption of the organ is increased, the blood supply is so great that each cubic centimeter of blood gives to the tissues less oxygen than usual. Increased blood supply to an active organ is due either to an increase of the general circulation rate which increases the blood flow through all the organs, or to changes in the distribution of the blood between the various organs, more blood being diverted to the active and less to the resting organs

Our knowledge of the nervous control of the blood vessels dates from Claude Bernard's discovery that nerve fibres run in the sympathetic chain which maintain the vessels in a state of tonic constriction. Section of these nerves leads to a considerable vasodilation and therefore to an increased blood flow; stimulation of them causes vasoconstriction. A few years after this discovery it was found that there are also vasodilator nerve-fibres which are antagonistic in function to the vasoconstrictor nerves, and that these nerve-fibres also have in many cases a constant influence on the blood vessels, section of them slightly diminishes the blood flow, and stimulation greatly increases it. The blood vessels are therefore, like the heart, under the influence of double innervation The tonic state of the blood vessels does not itself depend on nervous control, and it does not completely vanish after section of all the nerves going to an organ. The function of the vasomotor nerves is merely to increase or decrease this tone.

It can easily be shown that the continuous stream of impulses descending to the blood vessels along the vasoconstrictor fibres originates in the central nervous system If the spinal cord of a dog is divided below the medulla, the blood pressure falls from about 120 mm. of mercury to about 50 mm. Stimulation of the divided spinal cord immediately causes an increase in blood pressure, which may be as high as 280 mm. or more. Section of the central nervous system above the medulla has no lasting effect on the blood pressure. As the result of these experiments we may say that the vessels of the body are kept in a state of increased tone by impulses arising in the medulla. The portion of the medulla concerned with sending out these impulses is spoken of as the *vasomotor centre*. The activity of this centre is constantly under the influence of various afferent stimuli originating within the various organs of the body or as the result of excitations of higher or lower parts of the central nervous system.

The Vasoconstrictor and Vasodilator Fibres.—The vasoconstrictor fibres leave the spinal cord in the thoracic region. They have a cell station in the ganglia of the sympathetic chain, and are then distributed along various nerves, to the organs. The most important vasoconstrictor nerve is the splanchnic nerve, which supplies all the abdominal organs.

The typical vasodilator nerves take their origin from various parts of the central nervous system Thus the vasodilators to the salivary glands and tongue are distributed with the cranial nerves, and probably originate from the nervus intermedius between the seventh and eighth cranial nerves The nervi erigentes going to the genitalia leave the lower end of the cord by the anterior roots of the second and third sacral nerves. The vasodilator fibres going to some of the abdominal organs and to the extremities have the same origin and course as the ordinary sensory nerves Since the vasodilator impulses pass along these nerves in a direction opposite to that taken by the normal sensory impulses, they have been termed *antidromic* impulses. This appears to be one of the few cases in mammals in which the same nerve fibre performs two different functions.



The vasodilator and vasoconstrictor fibres are generally mixed in common trunks innervating an organ, and it is only by special means that they can be functionally separated.

Peripheral Tone of the Blood Vessels.—It has been mentioned above that the function of the vasomotor nerves is only to change the tonic condition of the blood vessels; the tone itself does not disappear, however, even after complete denervation. This peripheral tone of the blood vessels is considerably influenced by the composition of the blood, especially the oxygen tension, the degree of alkalinity, and the presence of vasoconstrictor substances which are normally secreted by the pituitary and the suprarenal glands. Whether the nerves are intact or severed, the capillaries of the body are never all open at the same time The capillary bed seems to be, at least in some organs, in a perpetual state of variation. Capillaries constantly close and open so that blood flows through various channels. Whenever the oxygen tension of the blood diminishes, the blood vessels dilate, a large number of capillaries open, and the blood flow through the organ increases; excess of carbon dioxide has the same effect.

On the other hand, an increase of the pituitary secretion or of adrenaline in the blood increases the tone of the blood vessels and capillaries. Some authors regard these two substances as being primarily responsible for the peripheral tone of the blood vessels in general. Superimposed upon these perpetual variations of the peripheral tone is the effect of the vasomotor nerves, and it often happens that agencies which would affect the peripheral tone in some definite direction are prevented from doing so on account of antagonistic influences from the vasomotor centre. For instance in the case of increased carbon dioxide tension of the blood, the carbon dioxide acting peripherally tends to dilate the blood vessels, but it is also a strong stimulus to the vasomotor centre and excites the vasoconstrictor fibres to such an extent that the blood vessels constrict; the blood pressure then rises until the central nervous system succumbs to the toxic effect of the carbonic acid.

The Vasomotor Centre.—Besides being sensitive to carbon dioxide and to the acid products of metabolism which accumulate in consequence of lack of oxygen, the vasomotor centre is constantly influenced by impulses arriving from the sense organs on the surface of the body and from various other organs. Amongst these, impulses originating in the vascular system are the most important, and are practically the only ones which have been studied. The afferent stimuli may be of two kinds. First are those which affect the vasomotor centre in such a way as to cause vasoconstriction either in some definite organ or in many organs; in the latter case the general vascular resistance increases and the arterial pressure rises. These afferent impulses are described as *pressor impulses*. On the other hand, impulses may reach the vasomotor centre which will lead to a vasodilation; this again may be restricted to a small area or may involve sufficient blood vessels to bring about a fall in the arterial blood pressure. These are known as *depressor impulses*.

Pressor reflexes can be evoked by stimulation of almost any of the sensory nerves of the skin, the digestive tract or other abdominal viscera. The chief depressor nerve originates in the heart and in the first part of the aorta. In the rabbit this nerve runs in a separate and easily accessible trunk. Stimulation of the central end of the depressor produces such a large dilation of most of the blood vessels that the arterial blood pressure

FROM STARLING, "ELEMENTS OF HUMAN PHYSIOLOGY" (J. & A. CHURCHILL)

FIG 22.—BLOOD PRESSURE TRACINGS TO SHOW INFLUENCE OF CHANGES IN THE CIRCULATION THROUGH THE BRAIN ON THE ACTIVITY OF THE VASOMOTOR CENTRE

falls to a very low level. In the intact animal the physiological stimulus which brings this depressor mechanism into operation is the high blood pressure in the aorta. Distension of the aorta by pressure stimulates the depressor nerve and leads to a compensatory dilation of arterioles and to a fall in pressure. The nerve can be regarded as a safety valve which prevents excessive rises of blood pressure.

It is highly probable that in the case of an excessive fall of pressure another reflex mechanism comes into action, a pressor reflex which also originates in the heart and aorta and which tends to antagonize the fall. Recently it has been shown that the carotid artery at the point of its division into the internal and external branch is also sensitive to pressure. Increase of pressure in this part leads to a reflex vasodilation, and fall of pressure leads to a vasoconstriction. Besides these two influences, it seems that the vasomotor centre itself can be excited or inhibited by variation in the blood pressure. Fig 22 gives an example of the effect on the general blood pressure of changes in the pressure of the brain (which was perfused through the carotid arteries).

Thus we see that the organism possesses several mechanisms by means of which it can keep the blood pressure constant and counteract any influences which would tend to raise or lower it. In the case of haemorrhage, a considerable amount of blood may be removed from the body, but the blood pressure soon returns to the normal. Blood may be withdrawn from the system slowly to the extent of about 4%, or rapidly to the extent of about 2% without lowering the arterial pressure, owing to the compensatory constriction of the arterioles. Such withdrawal of blood, though it does not affect the blood pressure, will greatly diminish the intensity of the circulation and will reduce the output of the heart. Conversely, injection of salt solution (0·9%) or transfusion of blood will not, within certain limits, affect the arterial blood pressure owing to compensatory vasodilation. Transfusion will, however, increase the circulation of blood and thus lessen the harmful consequences of haemorrhage. Considerable haemorrhages will not be effectively compensated and will therefore lead to fall of blood pressure, and transfusion will be absolutely necessary to save the animal from death.

Since most blood vessels are innervated by vasoconstrictor and vasodilator fibres, it is obvious that a pressor or depressor reflex could be carried out by several means. Vasodilation could for instance be produced by means of a reflex inhibition of the vasoconstrictor tone, or by a stimulation of the vasodilator fibres which would depress the tonic state of the blood vessels. What actually happens is that the two sets of fibres in all known cases act in a reciprocal fashion. Thus a depressor reflex involves a simultaneous diminution of the vasoconstrictor influence and increase of the vasodilator influence, and vice versa in the case of a pressor reflex.

Chemical Factors.—In recent years there has been a considerable accumulation of facts which show that various chemical factors affecting the blood vessels, apart from any nervous influence, are of great importance for the regulation of the circulation, and that these factors can exercise their action either on the arterioles or on the capillaries.

It is known for instance that in many conditions, *e.g.*, pain, asphyxia, the physiological state that accompanies emotion, there is a considerable rise in the production of adrenaline by the suprarenal glands. Adrenaline, as has been mentioned before, stimulates the nerve endings of the sympathetic nervous system, and it therefore also stimulates the nerve endings of the vasoconstrictor nerves. Thus, in all cases associated with increased production of adrenaline, there is widespread vasoconstriction and a rise in the blood pressure, this vasoconstriction is independent of the integrity of the vasomotor nerves. In the case of activity of an organ, vasodilation occurs in most cases not on account of concurrent depressor reflexes but on account of the production of chemical substances within the organ. These substances mainly affect the tone of the capillaries, and in their presence a great number of hitherto closed capillaries open or dilate widely. It has been shown that in the case of a contracting muscle the capillaries may be increased from 2% to 15% of the total volume of the muscle.

There is, however, one substance which may possibly be produced in the organism under normal conditions, and which is known to have a powerful capillary dilator effect. This substance is histamine, a product of the amino-acid histidine, which is a normal constituent of most proteins. It has been suggested that the production of histamine plays an important part in giving rise to the symptoms of "surgical shock." In this condition there is a universal dilation of the capillaries, and therefore a fall of blood pressure and a diminution of the amount of blood in circulation which finally leads to death. This condition, which occurs after laceration especially of muscles, can easily be reproduced by injection of large doses of histamine.

The mechanism of adaptation of the circulation in various organs to their needs must at present be regarded as in part dependent on the delicate balance of the nervous vasodilator and vasoconstrictor influences, which modify the tone chiefly of the arterioles, and also on chemical substances produced locally as the result of activity, which modify the tone of the capillaries.

The Portal Circulation.—The portal circulation is peculiar in that the blood passes through two sets of capillaries. Arterial blood is conveyed to the capillary networks of the stomach, spleen, pancreas and intestines by branches of the abdominal aorta. The portal vein is formed by the confluence of the mesenteric veins with the splenic vein, which together drain these capillaries. The portal vein breaks up into a second plexus of capillaries within the substance of the liver. The hepatic veins carry the blood from this plexus into the inferior vena cava. The portal circulation is largely maintained by the action of the respiratory pump, the peristaltic movements of the intestine and the rhythmic contractions of the spleen; these agencies help to drive the blood through the second set of capillaries in the liver. Obstruction in the right heart or pulmonary circulation at once affects the circulation in the liver. The increased respiration which results from muscular exercise greatly furthers the hepatic and portal circulation.

The Cerebral Circulation.—The circulation of the brain is

somewhat peculiar, since this organ is enclosed in a rigid bony covering. The limbs, glands and viscera can expand considerably when the blood pressure rises, but the expansion of the brain is confined. By the expression of venous blood from the veins and sinuses, the brain can receive a larger supply of arterial blood at each pulse. Increase in arterial pressure increases the velocity of flow through the brain, the whole cerebral vascular system behaving like a system of rigid tubes when the limits of expansion have been reached. The pressure of the brain against the skull wall is circulatory in origin; in the infant's fontanelle the brain can be felt to pulse with each heart-beat and to expand with expiration. The arterial supply to the brain by the two carotid and two vertebral arteries is so abundant, and so assured by the anastomosis of these vessels in the circle of Willis, that at least two of the arteries can be tied without grave effect. Sudden compression of both carotids may render a man unconscious, but will not destroy life, for the centres of respiration, etc., are supplied by the vertebral arteries. The vertebral arteries in their passage to the brain are protected from compression by the cervical vertebrae.

Whether the muscular coat of the cerebral arteries is supplied with vasomotor nerves is uncertain

The Coronary Circulation.—Extremely peculiar conditions exist in the coronary circulation, *i.e.*, the blood supply to the heart muscle itself. The coronary arteries originate at the root of the aorta. They turn back into the substance of the cardiac muscle and break up into a rich meshwork of capillaries which convey the blood into the coronary veins, the majority of which collect the blood into the coronary sinus, while some open on the inner surface of the chambers of the heart (Thebesian veins). During systole the heart muscle develops a pressure which must be higher than that in the aorta, as otherwise no ejection of blood from the ventricle into the aorta would be possible. The coronary arteries, which are at any time distended by the pressure prevailing in the aorta, are thus compressed, and during systole the inflow of blood into those of the left ventricle is stopped. The right ventricle by its weak contraction only affects the coronary circulation to a slight extent. While restraining the inflow of blood into the coronary arteries, the contraction of the heart greatly facilitates the outflow from the veins by mechanically expressing their contents. It is interesting to note that adrenaline, which greatly increases the strength of the cardiac beat, also produces a great dilation of the coronary blood vessels, so that a larger amount of blood is provided to meet the increased expenditure of energy. The coronary blood vessels are richly provided with vasodilator and vasoconstrictor nerves, the sympathetic supplies the vasodilator, and the vagus the vasoconstrictor fibres.

Since the coronary blood flow is so readily affected by the heart beat, great difficulties are encountered in the study of the regulation of the coronary circulation. A knowledge of all the influences affecting it is, however, extremely important because the activity of the heart, and therefore the fate of the organism, ultimately depends on the blood supply to the cardiac muscle. It is known that even temporary occlusion of the coronary blood vessels is fatal. The disease known as *Angina pectoris*, which usually leads to death, is most probably due to such occlusion as the result of arteriosclerosis or thrombosis of the arteries; it is highly probable that in some cases it may also be due to disorders of the nerves which regulate the tone of the coronary blood vessels. In most cases of weakening of the heart, the coronary flow increases. Lack of oxygen produces an enormous augmentation of the coronary circulation, thus ensuring the survival of the heart so long as there is a trace of oxygen left in the blood.

The Influence of Posture on the Circulation.—The circulation remains efficient not only in the horizontal but also in the erect position. Yet in a man standing six feet high the hydrostatic pressure of a column of blood reaching from the vertex to the soles of the feet is equal to 14 cm. of mercury. The blood, owing to its weight, continually presses downwards, and under the influence of gravity would sink if the veins and capillaries of the lower parts were sufficiently extensile to contain it. During the evolution of man, there have been developed special mechanisms by which the determination of the blood to the lower parts is prevented, and the assumption of the erect posture rendered possible. The abdominal viscera are slung upwards to the spine, while below they are supported by the pelvic basin and the wall of the abdomen, the muscles of which are arranged so as to act as a natural waistband. In tame hutch rabbits, with large pendulous abdomens, death may follow in from 15 to 20 minutes if the animals are suspended and immobilized in the erect posture, for the circulation through the brain ceases, and the heart soon becomes emptied of blood. If, however, the capacious veins of the abdomen be confined by an abdominal bandage, no such result occurs. Man is naturally provided with an efficient abdominal belt, although this is often rendered toneless by neglect of exercise or gross and indolent living. The splanchnic arterioles are maintained in tonic contraction by the vasomotor centre, and thus the flow of blood to the abdominal viscera is confined within due limits.

The veins of the limbs are broken into short segments by valves, and these support the weight of the blood in the erect posture. Every contraction of the skeletal muscles compresses the veins of the body and limbs, for these are confined beneath the taut and elastic skin. Guided by the valves of the veins, the blood is by such means driven upwards into the venae cavae.

Circulation During Muscular Exercise.—An attempt to understand the changes in the circulation during muscular exercise can only be made if every part of the complex regulation of the cardio-vascular system is kept in mind.

In muscular exercise, every available mechanism concerned in the regulation of the blood flow is brought into operation, everything being centred on the achievement of two objects, (*a*) to carry the all important oxygen to the muscles, and (*b*) to remove the excess of waste products as quickly as possible. In violent exercise the common effort of all the cardio-vascular mechanisms involved is often inadequate, but fortunately the muscles and other organs do not require an immediate supply of sufficient oxygen to fulfill their needs; fortunately also the muscles can withstand a certain degree of accumulation of waste products without much alteration of the intensity of the activity. In other words the muscles can to some extent run into debt as regards the oxygen supply. But the excess oxygen requirements must at some time be made good, or the activity will have to stop. The complete adaptation of the vascular and respiratory systems, when the oxygen supply and the removal of waste products entirely meets the demand, is achieved comparatively slowly. The first period of severe muscular activity proceeds under somewhat less favourable conditions than hold after complete adjustment has been attained. This is probably the explanation of the phenomenon of "second wind." The organism is better adapted to exercise, the more rapidly this state of adjustment is reached.

Since the arterial blood is normally about 95% saturated with oxygen, not much extra oxygen can be obtained by increasing the saturation of the haemoglobin. As already explained, the muscle obtains the required oxygen in two ways: (*a*) by increased utilization of the oxygen of the blood, *i.e.*, by a greater desaturation of the haemoglobin, and (*b*) by an increase in the blood flow. The first factor alone would be inadequate even if the muscles were able to remove all the oxygen from the blood. A simple example will serve to illustrate this. If we take the total blood flow as 4·5 litres per minute, even if we make the impossible assumption that the whole of the blood goes through the muscles, it will mean that the muscles will only be supplied with about 800 cc. of oxygen per minute. Now the normal oxygen requirements at complete rest are about 300 cc. per minute, and during severe exercise they may rise to 3,000 cc. per minute or more. Moreover, the desaturation of haemoglobin is never carried to completion, and even during severe muscular exercise the venous blood still contains some oxygen. Thus the increased oxygen demand can be met to only a limited extent by increasing the coefficient of the oxygen utilization.

The second factor, namely the increase in the output of the heart, is far more important. Amongst all the factors involved in this increase in the blood flow, we will first consider the heart. This organ plays only a subordinate rôle. The output of the

heart depends on the inflow and, under normal conditions, changes in the activity of the heart have little or no effect on blood flow. The main factor in the augmentation of the inflow concerns the peripheral blood vessels. Considerable changes in the heart beat must, however, take place in order to make it possible for the heart to cope with the larger inflow. The first effect of the larger inflow will be to increase the filling of the heart and therefore the output on account of the stronger beat. This is a purely automatic reaction of the cardiac muscle, and is independent of the central nervous system. The adaptation of a denervated heart stops at this point. The limit to this adaptation of the heart muscle is set by the pericardium The adaptation of the innervated heart does not, however, stop here The increase in the strength of contraction in this case is out of proportion to the inflow, so that the heart becomes able to give progressively stronger beats. It is not only more filled in diastole but it also empties better during systole This additional strengthening of contraction depends on the diminution of the influence of the vagus nerve, and on the excitation of the augmentor fibres of the sympathetic nerve.

But usually in addition to this increase in strength of the beat there is a quickening of the heart rate. This is also based in the first instance on a diminution of the vagus tone, and probably in most cases on an augmentation of the sympathetic tone. Further increase of the inflow is therefore met by a corresponding quickening of the heart beat The acceleration of the heart in muscular exercise is a purely reflex phenomenon, based (especially at the beginning of the exercise) partly on impulses descending to the cardiac medullary centres from the cortex of the hemispheres, which are probably conditioned reflexes. In part the acceleration is due to concurrent changes in the respiratory activity and to reflexes originating within the vascular system of the animal itself. We have seen that each inspiratory phase is accompanied by a diminution of the vagus tone and hence by an acceleration of the heart. Thus if there is a greater number of respirations per minute, the periods of acceleration become more frequent and finally fuse, so that the periods of retardation typical of the expiratory state have no time to develop.

Amongst the reflexes which affect the cardiac rhythm and which originate within the organs of the body itself, the reflexes from the heart should be considered first It has been shown by several observers that an increased inflow into the heart brings about a reflex acceleration of the heart beat. Changes in the activity of the heart should not be regarded as the cause of increased intensity of circulation, but as an adaptation which enables the increase to be performed.

The chief causes of increased total blood flow during muscular exercise can be grouped under the following headings:

1. The increase in the aspiration by the thorax;
2. The pumping action of the contracting muscles;
3. The increase in the amount of circulating blood;
4. The diminution of the total vascular resistance

To these should be added the factors which are not likely to affect the total blood flow, but which alter the distribution of the blood between the various organs These are:

1. The constriction of the splanchnic area;
2. The dilation of the blood vessels of the muscles.

These factors have all been discussed in the preceding pages and need only be mentioned shortly. The increased and more frequent expansion of the chest, which follows the deepening and acceleration of respiration, accentuates the negative pressure in the thorax, and tends to diminish the pressure in the large veins. These are therefore more quickly and more completely filled with blood from the periphery. The working muscles expel, by each contraction, blood from their capillaries to the veins, and thus actively help the propulsion of blood into the heart The spleen contracts and empties its blood into the vascular system, and an extra amount of blood thus becomes available. The dilation of the blood vessels in the muscles is so intense that the general resistance diminishes and the blood passes from the aorta into the venous system at a considerably faster rate. All these factors are helped by the contraction of the splanchnic vascular area, which diverts the blood to the muscles. The blood vessels in the muscle dilate, and the capillaries open so that the capillary bed in the muscles may increase 40 to 100 times during maximal activity. This dilation is chiefly if not exclusively due to the local production of vasodilator substances. It is not at present known how far the vasomotor innervation participates in this dilation.

Thus we see that during muscular exercise the organism meets the demand for an increased oxygen supply to the muscle by an intricate series of correlated mechanisms. The necessary adjustments involve the respiratory system and the whole cardio-vascular system, and probably afford one of the finest examples of co-ordination that has yet been discovered in the realm of physiology.
